March 5, 1975.

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

MR. GENEST: Mr. Commissioner, I thought I should tell you at the opening of today's hearing that Mr. Marshall and I, in order to prepare, to do our preparation for the opening of our case next Tuesday, as I understand (we're not going to sit on Monday because of Election Day), we'll be leaving your presence tonight, leaving Mr. Carter to represent Arctic Gas. I do so with regret and I ask you, sir, to excuse us for that purpose.

THE COMMISSIONER: Yes, certainly, Mr. Genest. The Inquiry will be carrying on each day this week, to and including Saturday, but we will not resume on Monday of next week; instead we will resume on Tuesday at 9 A.M. next week. Monday is Election Day here in the Northwest Territories, and out of deference to the electoral process here in the Territories, I think the Inquiry should not sit that day. I understand some people connected with the Inquiry may, for all I know, be anxious to be otherwise occupied on that day. Mr. Scott?

MR. SCOTT: Mr. Commissioner, I assume that as a result of that, Mr. Genest will be away until Tuesday; but in fact he is probably running in the election to take back the appointed seat which was given to him by his friends in Southern Ontario.

MR. GENEST: There was a large constituency there.

1 THE COMMISSIONER: I thought
2 he was going to Alberta. There is an election there,
3 too.

4 MR. SCOTT: Mr. Commissioner,
5 one matter I would like to deal with that relates to
6 corrections in the transcript. It is inevitable, not-
7 withstanding the excellent reporting services we have,
8 that corrections in the daily transcript will be
9 required. With respect to the overview evidence, we
10 propose to forward to each of the participants a copy
11 of their transcribed remarks in due course and invite
12 them to make whatever corrections of substance are
13 required, and return it to us.

14 We are also asking them to
15 forward to us photo prints of all the slides they use
16 which will be bound and we are asking them to insert
17 in the text of their remarks a reference to each of
18 the slides as appropriate by number so that in reading
19 the overview evidence it will be possible to turn
20 directly to a photoprint of the slide that the speaker
21 referred to at the moment when he referred to it.

22 Now with respect to corrections
23 that may be necessary, beginning next week when the
24 evidence begins, I want to make two points:

- 25 1. First of all, each participant will be responsible
26 for reviewing the transcript on a weekly basis
27 and submitting corrections. That is to say that
28 on Monday morning or on Monday when the Inquiry
29 begins at two o'clock, each week, each counsel
30 who has corrections will be expected to submit

L.C. Bliss
In Chief

1 them to the reporters for the period Friday to
2 Thursday of the preceding week . Those correc-
3 tions, I should emphasize, will be restricted to
4 corrections of substance and notwithstanding the
5 well-known intentions of counsel, it will not be
6 possible to add or subtract oratorical or rhetori-
7 cal flourishes or to introduce grammatical changes
8 unless they affect the substance of the question
9 or the answer given. Now these corrections
10 will be published each week, I suspect, either
11 on Monday or Tuesday, and each counsel will again
12 be responsible for reviewing the corrections to
13 determine whether they have any objections to
14 the corrections proposed by others. If they have,
15 they should be brought to our attention immediately
16 and they will have to be dealt with in some
17 fashion by the Commission, if there are disputes.
18 That matter has been discussed with counsel, Mr.
19 Commissioner, and if you're satisfied, I think that
20 is the procedure that should be adopted.

21 Mr. Commissioner, our next
22 overview witness is Professor Lawrence C. Bliss.

23
24 LAWRENCE C. BLISS, sworn:

25 THE SECRETARY: State your
26 full name.

27 A Lawrence C. Bliss.

28 DIRECT EXAMINATION BY MR. SCOTT:

29 Q Dr. Bliss, I was infor-
30 mally criticized last night by counsel for Arctic Gas

L.C. Bliss
In Chief

1 about the narrowness of my request for information as
2 to background. So this morning I intend to reform.

3 I take it that you are presen-
4 tly a Professor of Botany at the University of Alberta.

5 A That's correct.

6 Q And are the director of
7 the Devon Island project.

8 A Yes.

9 Q What is the Devon Island
10 project?

11 A This was a large integra-
12 ted ecological study that was a part of the Internation-
13 al Biological Program that functioned for five years
14 of field research. This is a study that's just been
15 completed.

16 Q Yes. You are the Director
17 of the Controlled Environment Facility?

1 A Yes.

2 Q What is that?

3 A These are the growth
4 chambers, animal facilities, greenhouses, aquaria
5 at the University of Alberta, Biological Science
6 Building, these facilities are used by different
7 departments and for better or worse I chair the whole
8 program.

9 Q Yes, well, now I under-
10 stand that you obtained your PhD. at Duke University
11 in 1956.

12 A That is correct.

13 Q What is your field?

14 A Plant ecology.

15 Q Yes, and following that
16 you have been on the staff at the University of
17 Illinois and the University of Alberta --

18 A That is correct.

19 Q -- and that you belong,
20 without detailing them, that covey of societies to
21 which members of your profession attach.

22 A That is correct.

23 Q Now, Dr. Bliss, have you
24 been engaged in any arctic field work in connection
25 with your specialty?

26 A Yes, beginning with my
27 PhD. research in 1953, having spent that summer on
28 the north slope in Alaska.

29 Q Yes, and in the last
30 20 years have you been, from time to time, in the Arctic?

A Yes.

Q How often? And on
what?

A That is right -- the
summer of '53 and then consecutively from the
summers of '69 through '74. In the meantime working
primarily in alpine areas in North America, and the
southern hemisphere.

Q Yes, now I take it that
you have done some work for the Environment Protec-
tion Board, a participant before the Inquiry?

A Yes, that is correct.

Q Would you briefly
outline the nature of your duties for them?

A Duties basically centred
around the inputs related to the plant ecological
component of our total review of the environment.

Q Yes.

Now, Dr. Bliss, I would ask
you to carry on as you wish.

A Mr. Commissioner,
ladies and gentlemen, yesterday we heard in detail
about things that I would like to build upon, in the
sense of terrain, permafrost and river hydrology.

Biological systems play a
fundamental role directly and indirectly in our
everyday lives, whether we realize it or not. Directly
we are all aware of this from the standpoint of the
food that we eat, that is either produced directly by
plants, are then consumed by animals and then we eat

1 them.

2 In turn, the plant fibres
3 that we use in a multitude of ways. Indirectly
4 though, plants and animals, but especially plants,
5 play a very fundamental role in the whole functioning
6 of the biosphere in the terms of gas exchange, in that
7 plants use carbon dioxide in photosynthesis, and
8 release, just like all other organisms, oxygen, I
9 should say release CO₂ then in respiration and use
10 oxygen as well in that process.

11 So that in terms of the total
12 functioning, plants tie up carbon dioxide and then this
13 gets released in the process of respiration.

14 In turn, as we heard from
15 Dr. Church yesterday, another key role that plants
16 play is the loss of water or transpiration. This
17 becomes very important in bog situations and others
18 in the North, bits and pieces of that will come out
19 today in the discussion.

20 In turn, they play a very
21 fundamental role in the cycling of nutrients. Basic-
22 ally these are contained in the soil, either in mineral
23 or organic soil, plants utilize these to varying degrees
24 and in turn animals from this and related to that then
25 of course, many small organisms in the soil that break
26 down organic matter in decomposition making these
27 nutrients available then to future populations of
28 plants and animals.

29 So that in terms of the

functioning of biology of landscape there are many interactions that are essential to our activities.

Basically, the gathering of scientific information is essential if we are to understand many of these processes, either on a very broad scale or in fact as a detailed set of studies such as we have done on Devon Island which we are not going to talk about here, but some of that kind of information is applicable back in a variety of ways.

In order to understand the fluctuations in plant and animal populations we must study these for a number of years. One of the problems that we face as biologists is that many times we are asked for answers, we need to provide them in the next few days and in the next month or so and many times this is not possible because we must study a population of caribou or the plant regrowth after fire or after slumps, for a period of years before we have sufficient information to make value and scientific judgments. So that sometimes our analysis seems slow, but it is because the things that we deal with in the biological fluctuations from year to year force us, in many ways, to deal at this level.

Until about five to six years ago, the amount of information from the North, our northern forests and arctic were bits and pieces of information. Important bits and pieces, but most of it done by small isolated groups of people working in

L.C. Bliss
In Chief

1 relatively isolated areas and it is because of two
2 major events that in the last group of years I feel
3 that we have been able to advance our knowledge very
4 significantly.

5 These two things are, the
6 one that was referred to earlier, this International
7 Biological Program, where very intensive studies were
8 done in small areas by a multitude of people for
9 five years. A study that has already been referred to
10 on Devon Island, another equally large study that is
11 more applicable in terms of the things that we are
12 talking about here at Barrow, Alaska, and even other
13 things that can be related in terms of a large
14 grassland study in Saskatchewan.

15 Secondly, then, are the stud-
16 ies that have been funded by industry, Government, some
17 of which have been conducted via grants from universi-
18 ties, directly related back then to this application
19 in these hearings.

20 These kinds of studies deal
21 primarily in the broad area of inventory, we make no
22 apology for this, because if there are vast areas that
23 we know relatively little about, we have to start at
24 this level of gathering the broad basic data of what
25 are the plants and animals, where are they found,
26 in what numbers, what are their cycles, things of
27 this kind.

L.C. Bliss
In Chief

1 It is only after we have a
2 reasonable amount of information of this kind that we
3 can then push on to these more complicated sophisto-
4 cated kinds of studies where we're involved with eco-
5 system research. In many ways it would have been
6 improper for us to have been involved in great details
7 at that level, considering the things that were needed.

8 The basic business then of the
9 last five years that has brought a lot of attention,
10 is the fact that much more money has been available
11 for the study. This has been a much more integration
12 then of the research effort, and in turn there were
13 clear-cut research objectives to be met.

14 In terms of this morning's
15 presentation, then, I have basically two objectives
16 in this exercise.

17 The first, sir, is to acquaint
18 you and the audience with some of the concepts and
19 language that we use in plant ecology, and this whole
20 business then of trying to understand complex biological
21 systems or eco-systems.

22 Secondly then, to illustrate
23 much of this in terms of the plant communities, the
24 vegetations, and essentially the border of Alberta,
25 Northwest Territories to Prudhoe Bay, Alaska. In the

26 course of that, then, to discuss some of the inter-
27 actions of plants with climate, with soils, with
28 terrain, and to comment briefly in terms of wildlife,
29 although obviously the other speakers that will follow
30 will go into this in much greater detail; and

L.C. Bliss
In Chief

1 certainly not to leave out the roles that people play
2 in terms of living off the land. Bits and pieces of
3 this will be referred to as well.

4 If we may have the lights
5 down, please, then, and the slide projector on, for the
6 first two slides; this very first one is a vegetation
7 map of Canada. We are concerned with this portion up
8 here but I felt that we should start by getting some
9 overall impression of the fact that in Southern
10 Saskatchewan and Alberta we have these grassland
11 areas pictured here in yellow. Beyond that, then, is
12 a transition from grassland to forest, the so-called
13 aspen parkland, where there is really a sea of grass
14 but with scattered clumps or islands of trees, Alaskan
15 trees, this light green area. To the north of that,
16 then, the closed Boreal Forest, the coniferous
17 forest stretching all the way across the continent in
18 this dark green band.

19 To the north of that then,
20 open forest, the so-called forest tundra, lichen
21 woodland, or as used by some people, sub-Arctic. That
22 is this light green belt stretching across all the way
23 in essence to the mouth of the Mackenzie River.

24 The white areas north of that
25 then are the Arctic. We will be dealing only with the
26 mainland situation. For the record I would like to
27 point out that although we frequently refer to every-
28 thing north of the 60th Parallel as the Arctic, bio-
29 logically, ecologically, technically this is not
30 correct, in the sense that the Arctic really refers

L.C. Bliss
In Chief

only to this northern portion, the treeless portion, this band should then be referred to as forest tundra or sub-Arctic, and this portion then as the Boreal Forest.

So this morning, sir, we will be concentrating then on these three main units, plus the component of alpine tundra that occurs in the mountains.

The next slide then, please, shows in greater detail than this pattern of these major units of vegetation along the route, with closed Boreal Forest extending up along the river as far as Norman Wells. In general in an area with this continuous permafrost from Norman Wells on north then into the forest tundra or open forest, as we will see, in which in general there is continuous permafrost through the mountains, alpine tundra, the brown area, in terms of a potential inland route, or then a coastal route, the yellow areas being lower slopes, foothills, coastal plain, herbaceous vegetation, or in terms of ^{the base of} the Tuk Peninsula and up onto Richards Island, where low shrubs in terms of a foot or so in height predominate, much of the rest of the presentation then will concentrate on these sorts of things. If we may have that one off, please.

I want to start, though first, by going over some general things in terms of background information, as I said, related to some of our jargon terminology, so you'll have a better feeling for this, and to start with this business then of

L.C. Bliss
In Chief

1 plant community.

2 Plants grow together in
3 assemblages, just as people many times occur together
4 in communities or societies. We have been studying
5 plants in this manner, their assemblages, what is
6 there, what are they like, for the last 100 years or
7 so but it is only in the last 20 to 30 years that these
8 have been studied in greater detail.

9 A forested area is one of
10 the best examples to think of. We're all much more
11 familiar with this, where there are trees, either open
12 grown or closed grown, frequently then with an
13 understorey of shrubs that are able to grow in the
14 reduced light that is provided as a result of this
15 canopy of trees. Under these and between these
16 shrubs then on the forest floor are scattered herbace-
17 ous plants, sometimes forming a closed cover as you
18 will see when we look at aspen groves, as opposed
19 to coniferous forests, where because of greatly reduced
20 light levels, a much lower soil Ph, the soils are
21 more acid, conditions are not as conducive to them so
22 that we get different assemblages in many fewer of
23 them, and in turn then on the forest floor very frequently
24 we uncover many cases of solid cover of mosses, again
25 especially if we're talking about a coniferous forest,
26 many fewer of these if we're talking about aspen or
27 poplar; and frequently associated lichen, not
28 only on the forest floor but also on the trunks of the
29 trees, as well as rotten logs.

30 So that one of the things we

L.C. Bliss
In Chief

1 do then, is to go into a community, try to determine
2 what is there in terms of the kinds, the numbers, their
3 stature in terms of height, their growth rate, and
4 numerous other things.

5 In terms of this, then, we
6 come to this next item of species diversity, where we
7 know that in different kinds of landscapes with different
8 kinds of climates, there are different numbers of plants,
9 pardon me. This is a very broad brush, look at this,
10 but at least it gives us some idea that where we're
11 dealing with a closed forest along the lower and
12 central Mackenzie, there are roughly eight species of
13 trees -- there are eight that can be found, not in
14 anyone place but collectively; that there are better
15 than 40 different kinds of shrubs that grow in these
16 forest communities, and on view as you see here, to
17 a total of around 400 species of not only flowering
18 plants but also of lichens and mosses.

L.C. Bliss
In Chief

1 As we go north then of the
2 closed forest into the forest tun/dra there is a reduction,
3 but not as dramatic as one might expect. In other words,
4 these northern landscapes that we normally think of as
5 being cold, severe, limited plant and animal develop-
6 ment, still have a reasonable number of kinds. Along
7 streams and the like we can still find five different
8 kinds of trees, still a reasonable number of shrubs,
9 and small shrubs, many herbs and actually an increase
10 then in this ground cover of lichens and mosses. This
11 plays a key role then back to some of the animals that
12 others will talk about later.

13 So that we need then some
14 idea, some understanding of the diversity of kinds of
15 plants, which is what we deal with in trying to sort
16 out how and why things are the way they are.

17 In all of our plant ecologi-
18 cal work, one of the key things to do, of course, is
19 not only determine what is there but try to get some
20 idea why and how. So that when we deal in this area
21 we immediately then begin thinking in terms of all of
22 these inter-actions. We have to deal with climate.
23 I, unfortunately did not hear Dr. Fyles yesterday
24 morning, I believe that he went into this at least
25 on a broad general scale; that's all that I intend to
26 do here, to basically point out that the growing season
27 is longer where we have forests than where we have
28 Arctic or alpine tundra. But the summer growing
29 season, even though there might be some nights with
30 frost, is frequently four to five months in the

L.C. Bliss
In Chief

1 forested areas, nearer 3 1/2 to four months in the
2 forest tundra, and in general in these Arctic areas,
3 both in Arctic tundra and alpine tundra areas the
4 growing season is nearer three to 3 1/2 months, on the
5 mainland.

6 In terms of summer temperatures,
7 July being the warmest month, as a generalization
8 throughout the world, trees reach their limit of growth
9 where the summer temperature of the warmest month is
10 roughly 50 degrees Fahrenheit. There are other things
11 that enter into this, but this is one of the key
12 components in terms of this; and it matters not whether
13 we're talking about conifers here, in the lowland areas,
14 up around Inuvik, in the mountains to the west, or in
15 fact if we're in other areas in the world where there
16 are different kinds of trees at their northern limit
17 or altitudinal limit.

18 Another key component here
19 of course is topography. This plays a very fundamen-
20 tal role in terms of the kinds of soils that develop,
21 soil moisture, soil drainage, the rate of decomposition,
22 the kinds of organic matter that may accumulate, and
23 the like, which of course immediately then relates back
24 to this business of soils. They are intimately inter-
25 twined along with the plants. The soils are an inti-
26 mate product of the kinds of plants that occur in the
27 area, their growth rates, the kinds of material that
28 the soils has developed from, depending on the kind of
29 rock, whether organic matter of the plants, how impor-
30 tant that role is, the basic kinds of nutrients that

L.C. Bliss
In Chief

1 are involved in them. This then in turn is tied up
2 intimately with the micro-climate of the situation,
3 not only below ground but above ground. In many areas
4 where there is variable topography, where there are
5 depressions, cold air will settle. It moves down-
6 slope so that there are cold pockets. Almost always
7 nightly or very frequent nightly frosts, there are
8 certain kinds of plants can tolerate that kind of
9 situation; there are others that cannot. So that this
10 as well as slope exposure, those slopes that face more
11 into the south having different vegetation, those on
12 other exposures and the slides that will follow will
13 go into some of these details.

14 In turn, animals play a key
15 role into these inter-relationships, very frequently
16 influencing the kinds of plants, or at least the magni-
17 tude to which they grow. I am reminded not so much
18 of our own north here, but very similar areas in
19 Scandanavia where there are large areas of birch, we
20 have limited areas of birch, but there there are certain
21 insects that have been feeding extensively on these,
22 defoliating the trees and making major changes, not
23 only in the forest composition but therefore in the
24 livelihood of the people, including reindeer manage-
25 ment in the last few years in some areas.

26 Another important item, then,
27 is this business of plant succession. The sequence of
28 changes of plants that occupy a given area over time,
29 this plays a very fundamental role then in our under-
30 standing of the north, not only in terms of basic

L.C. Bliss
In Chief

1 land management, but of course then back in terms of
2 what happens after fire, what happens after slumps,
3 what happens after the surface of the soil is distur-
4 bed. We have a another very generalized diagram that
5 will illustrate this a little bit and we'll come back
6 to this point then again later with the slides.

7 But in general, the sequence
8 in all of these northern areas you will see starts with
9 herbaceous plants, primarily with grasses, and many
10 times associated little herbaceous plants. In almost
11 all cases this then goes through a stage of shrubs
12 which may take 20 to 30 to 50 years, and finally then,
13 if we're talking about forested areas, in this part-
14 icular case we go into aspen and then on into white
15 spruce in an upland larea; along river bottom areas it
16 may go the sequence -- in fact it almost always does -
17 the sequence from tall shrubs to balsam-poplar, which
18 is a short-lived tree and is replaced then by white
19 spruce.

20 Along lakeshore areas and
21 poorly drained areas, rather than going into these
22 kinds of communities, it's a totally different sequence
23 with a very wet aquatic environment, lower Ph, mosses
24 become more important, especially sphagnum mosses,
25 plants that will grow in the shallow water, the so-
26 called emergent plants, which will lead then to the
27 development of sedge mass, low shrubs, and finally into
28 scattered black spruce. This kind of sequence may
29 take 200 years, while getting this sequence, especially
30 up to this kind of forest, may take only 30 to 40 years.

L.C. Bliss
In Chief

1 This then again plays a key role in terms of the rates
2 of change, the rates at which many of these processes
3 go on.

4 Forest tundra then again is
5 a slow process, very similar to this one we just
6 looked at where grasses and sedges frequently come in,
7 especially after a fire, followed by shrubs and again
8 scattered spruce.

9 Moving on north into the
10 tundra, especially into the low shrub tundra, which is
11 the easiest one to deal with here, again the sequence
12 from grasses, a few sedges, to low shrubs only a foot
13 or so in height. So that again, in terms of overall
14 inventory, in trying to figure out what grows where
15 and how, one has to be cognizant then of the fact that
16 much of the land will not be in a stable equilibrium
17 situation, but will be under this flux or change,
18 associated with past fires, past flooding, even past
19 human activities of various kinds; and we need to have
20 a basic knowledge scientifically of this, the rates,
21 the kinds of plants that come in, to know in fact how
22 to aid nature in the re-establishment of so-called
23 re-vegetation of some of these kinds of situations.

24 The next thing that I want
25 to touch on briefly then is a word that I used in the
26 beginning, it's a word that is used widely these
27 days but a difficult one to really conceive and get
28 much of a feeling for, and that's this business then of
29 an eco-system.

30 Basically an eco-system is a

L.C. Bliss
In Chief

1 study of the inter-actions, the functions and the
2 structure of an assemblage of plants and animals in a
3 given chunk of land. It includes some understand-
4 ing of the rates in which foods are produced by plants,
5 the rates of photo-synthesis, if you will, the rates
6 in which these products are either consumed by animals
7 on up the food chain, or released in terms of the
8 death of plants, the death of organisms, and decomposi-
9 tion. So that the basic components in an eco-system
10 study then includes intensive work with the environment,
11 the climate, both above ground as well as within the
12 soil. Work then with the plants that are growing
13 there, what are their rates of growth, in turn then,
14 what are the animals that are consuming the plants
15 or are themselves being consumed, as carnivores, and
16 finally then this huge complex that lives in the
17 ground, the soil complex. The thing that we know less
18 about; if there is one thing that I can admit, there
19 usually is in all of these large eco-system studies
20 that have been done throughout the world, not just the
21 ones we've done in Canada, the biggest mystery we
22 still/^{have} are the details, the intense details that
23 go on in this little box down here. It's small in
24 size but very complex biologically. We're talking about
25 things that grow very rapidly, bacteria may turn over
26 in a matter of a few hours. Some soil organisms may
27 take several years to mature. There are hundreds, there
28 are thousands of them, in many cases, and all of these
29 kinds of inter-actions.

30 It's the critters above the

L.C. Bliss
In Chief

1 ground that we can deal with more easily, and of course
2 as a result of this, these are the things that we have
3 the greatest amount of knowledge of. I merely ideal-
4 ized the diagram here to get across a few of these
5 key points, the fact that the system is driven by
6 solar energy, that is captured then by the plant, the
7 plants are using water and nutrients and oxygen from
8 the soil in their growth and development, that much of
9 the material that is produced then goes to this de-
10 composer, soil complex system. But a portion of that
11 is passed on as plant energy then to the herbivores,
12 those animals that eat your herbaceous vegetation.
13 In turn, these plants are using carbon dioxide in
14 photo-synthesis, and are releasing carbon dioxide in
15 respiration, using in that same way then oxygen. Plants
16 literally then release oxygen in photo-synthesis, they
17 use oxygen in respiration just as all animals do,
18 and the reverse, the thing that I put on here, plants
19 use carbon dioxide in photo-synthesis and like all
20 organisms release carbon dioxide in respiration.

21 So O.K., we have a group of
22 herbaceous animals, these, a few of which are fed then
23 upon the carnivores, it can be more complex than this
24 but again I'm only wanting to dramatize in its simplest
25 form, the kinds of inter-actions that go on so that we
26 have some understanding, so that when people talk
27 about eco-system studies or in fact a component of an
28 eco-system, we have some realization that it really
29 consists of one or several of these various components.
30

1
2 At this point then, with this
3 brief introduction in terms of a little bit about
4 what constitutes plant communities, some of the inter-
5 actions that go on within plant communities, some of
6 the interactions that go on within ecosystems, let's
7 now turn then to the major vegetation units, to
8 portions of these northern ecosystems and look at them
9 in far more detail. To begin with I want to show this
10 one generalized diagram though first, of the extent
11 of these various units in the north.

12 One of the concerns that I have
13 always is that we as biologists need to present informa-
14 tion in a sufficiently quantitative broad scale manner
15 that others can interpret this in the sense of the
16 magnitude of the kinds of things that we are dealing
17 with, and hopefully this very first illustration of
18 this will help to get this message across.

19 We have taken the data then
20 from the proposed route from Alberta to Prudhoe Bay
21 using the coastal route versus the inland route, the
22 sort of thing that appeared on one of those first
23 slides, and then put down the lineal miles as well as
24 the percentage of the land then that is in these
25 basic units, and as you can see, Sir, in terms of the
26 coastal route, it is roughly a third each of boreal
27 forest, of this open forest or forest tundra and then
28 this complex of both, in this case, of really just
29 coastal tundra, but subdivided into these two units
30 that we will talk about later.

1 In turn, dealing with the
2 inland route, there is a greater percentage of forest
3 Tundra and literally then a reduction in the amount of
4 true arctic tundra or mountain tundra, alpine
5 tundra, but in general the main theme here is that
6 these are large units of land in the north and there are
7 large components of each of these that we are dealing
8 with when we discuss these northern areas.

9 If we now then can take these
10 four main units and talk about them more in detail,
11 looking at slides and the like to illustrate this.
12 This very first one then illustrates the boreal forest
13 segment from the Alberta - N.W.T. border to Norman
14 Wells.

15 When one flies over this,
16 the appearance is that water is everywhere. There is
17 a lot of water, but in terms of the actual routing
18 itself, you can see that this is a smaller percentage,
19 the combination of open water and in fact of bogs and
20 fens than one might appreciate.

21 Why distinguish between these
22 two units? Well, again ecologically, in the wet lands
23 first of all, they are covered with peat but the
24 bogs have an acid peat, the product of spagnum mosses
25 and the acid products that they release as opposed to
26 fens which include more mineral soil and where there
27 is peat accumulation it is usually from sedges which
28 produce less acid conditions.

29 This then has a direct bearing
30 and relationship back then to the kinds of plants that

1 grow there, their growth rates, and even our potential
2 use of some of these landscapes. There is a portion
3 then, a fairly large portion along the river banks.
4 In turn there is a huge area of closed forest. Some
5 of it, in recent burns, much of it in mixed woods which
6 means that there have been past fires, so that it
7 scattered aspen poplar plus the conifers, we will see
8 slides to illustrate that in a minute, but it is a
9 fairly sizable percentage of the land. There is a
10 very small percentage of true closed hardwood, of
11 no conifers. We are too far north for the hardwoods
12 to be on their own, a very dominant feature. It is not
13 that kind of a climate. And in turn then, the
14 bulk of the land really is immature closed forest.

15 Another way of looking at
16 this rather than the percentages of what is there,
17 is then on a landscape basis of where are things
18 found, which is --

19 THE COMMISSIONER: Excuse
20 me, Dr. Bliss --

21 A Surely --

22 THE COMMISSIONER: That
23 last diagram --

24 A Yes --

25 THE COMMISSIONER: -- was the
26 route from Norman Wells south to 60, was it?

27 A That is correct.

28 THE COMMISSIONER: Yes --

29 A That is correct. And
30 we will take segments of this in terms of these major

1 vegetation types and repeat this process as we go.

2 This then is a complicated
3 thing, we do not have to worry about all the details,
4 but I wanted us to hone in on this a little bit again
5 before we look at pictures because individual koda-
6 chromes just give us a little glimpse of this and that
7 and the like, where we cannot necessarily see some
8 of these inter-relationships.

9 But in this southern portion
10 then, where we are talking about forested land, in
11 upland areas, sand plains and the like, there may be
12 forest of pine. I have indicated here only Jack Pine,
13 but in some cases, there can also be Lodge Pole Pine.
14 But in any case these are always well drained soils,
15 the soils are quite acid because of the kinds of
16 conditions that a pine forest produces. The organic
17 matter that decomposes is a very acid sort of producing
18 environment so that the soil pH drops.

19 Fire hazard is very high in
20 these forests. There is a lot of litter produced, it
21 is very inflammable, so fires are frequent. In terms
22 of below the ground, there is seldom if ever any
23 permafrost, that is not that kind of an environment
24 in which pine will grow. So that when you walk into
25 a pine forest you can almost automatically say, no
26 permafrost here. Even if it is in the area of poten-
27 tial discontinuous permafrost.

28 In other upland situations
29 though, and more typically one would find aspen or
30 a combination of aspen and spruce. Pure aspen or

1 mixed woods of aspen and spruce. Still upland areas,
2 well drained, various kinds of soils, pH relatively
3 acid, a medium fire hazard, not quite as bad as in
4 the Jack Pine and very frequently then, if there is
5 permafrost, it is at a fairly reasonable depth
6 relative to other things that we will see later, where
7 the active layer is usually at least three feet, a
8 meter or so in depth.

9 As we move to slopes, these are
10 frequently slopes that are a bit better drained. They
11 are warmer because of their exposure to the sun. As
12 a result of this the active layer is also relatively
13 deep and in many cases on these slopes then we find
14 essentially pure stands of spruce.

15 Once we move down to the river
16 terraces, there starts the situations that Dr. Church
17 was showing us yesterday. These are almost always
18 immaturity forests of white spruce. These are some
19 of the best forest stands in the north. This is where
20 lumbering is most feasible. Spruce grows best in
21 these kinds of situations. Because of flooding,
22 nutrient addition, the soils are coarse textured which
23 means that ^{if} there is permafrost it is at a relatively
24 deep level. There is usually enough bare ground around
25 so that the soils warm up reasonably well in the
26 summertime, so that it is a more favourable environ-
27 ment for plant growth, for tree growth.

28 I have indicated that shrubs
29 here again, because of this sequence of succession
30 from bare ground along gravel bars, back to the

1 closed forest. Finally into rolling land that is
2 so common from the air as well as on the ground, then
3 this combination of sedge fens and then open black
4 spruce. Very poorly drained areas, very low soil
5 pH, very acid conditions, where fire hazard is quite
6 low. There is not enough plant material to carry
7 fire and it is almost always wet, so that fire is
8 not nearly the hazardous thing there that it is in
9 these upland situations. /

10 If we can then please have
11 the slides, we will go through and look at some of
12 these.

13 This is an aerial view to
14 start with then at Fort Simpson, with the Liard River
15 coming in here. You can see a bit of the patterning
16 aspen, the lighter coloured trees, and actually Jack
17 Pine in through here. This is a sand plain, so
18 it is well drained. Here is a cleared area under
19 cultivation and this landscape then stretches for
20 miles beyond.

21 This is looking straight down
22 on a chunk of this kind of land which again illustrates
23 the mozaic pattern. Poorly drained areas, there is
24 a shallow lake filling in with sedges, a few shrubs,
25 grading back then into a combination of aspen, which
26 you can see here, even the lighter coloured trunks,
27 a bit of birch mixed in, and then back in this area,
28 a combination of white spruce and jack Pine, but a
29 considerable amount of Jack Pine on this raised area
30 here that is better drained, sandy soils.

You can see here then a

1 stand that is probably 50 years old or so. Aspen is
2 a marvelous species in the sense that it takes up
3 soil nutrients, uses them, produces leaves, the
4 leaves fall -- they are produced abundantly, they
5 fall and decompose rapidly. The product of this then
6 is that the forest environment is a very nutrient
7 rich one. So where there is Aspen, in the southern
8 portion this is the best potential land to clear for
9 cultivation because the soils are apt to be more
10 neutral and higher in nutrient content, therefore you
11 can rip off the trees and plant it to grass or even
12 to limited crops if the climate is warm enough.

You can see this business of succession going on here. A road is being built through this area, they've skinned this off a year or so earlier and yet aspen is re-sprouting from its roots. This is again one of the keys to aspen. It produces abundance of seed but it's rare to find a seedling of aspen. As a matter of fact I know a professor who used to tell his students, "I'll give any one of you an A if you can bring in an aspen seed." He never gave away an A. The seeds will germinate but only under very idealized situations; but the root stocks will live for years in the soil, after a fire goes through or a disturbance bang-up they come in a matter of a couple of years. So succession in a situation like this then is a very rapid phenomenon, even a little bit of fireweed in the immediate foreground.

A mixed stand then of mixed woods -- aspen and spruce coming in. This is an older stand. The aspen grows rapidly, takes over the site, it produces a relatively open forest; spruce on the other hand can grow in the shade of aspen, where aspen can't easily. So that aspen tends to be sort of a one-generation phenomenon, except for re-sprouting from the stocks on occasion, because it requires more light in photo-synthesis than does the spruce, so the spruce will come on later. It will eventually produce a closed forest, as you saw from the air before, and you'll see later on, produces a lot of shade, but spruce seed and seedlings can develop in the shade of a spruce forest because their light requirements to

manufacture food are much lower. So again in order to understand what goes on dynamically, we've got to know more than just what's there. We've got to know enough about these critters to know why they grow at the rates that they grow, and can then begin to predict what will happen with a chunk of land over time and that's the message of this.

Given another 50 years minus fire, that will be converted largely to a white spruce forest and there will be only scattered stands of aspen.

A stand of jack pine, typical of sandy soil, relatively short trees, limited value, spruce is of high value, especially these bottom land stands along river terraces. Commercially this is used in some places in North America, but only in a more limited manner. I should have commented that aspen is used, not as much as I predict it will be in the next 20 to 30 years. At Alberta we're very much concerned about this, in the sense of establishing enough research, to show how and how better aspen can be utilized because just as these landscapes that we're looking at here, there's a lot of aspen around. It grows relatively fast so that we need to be able to use it more effectively than we have, and studies have been shown that the wood fibre is a very good quality, can be made into paper; it may not be quite the same light color as pine or spruce, but it is still a very good quality for paper board, bags, brown bags and the like.

L.C. Bliss
In Chief

1 Here is a mixed stand then of
2 lodgepole pine. Lodgepole is relatively limited in the
3 area we're talking about, but in some upland situations
4 there is some of it present. It is more a component of
5 the mountains to the west.

6 Coming up again underneath
7 are some white spruce, so that with either aspen or
8 pine, if spruce can grow in the area it will eventually
9 take over because it's better adapted on a long-term
10 basis than is the pine. The pine again will not normally
11 -- seedlings will not normally develop in the shade of
12 a pine forest. That looks very light, and yet I
13 had to manipulate the camera and take it about a half
14 of a second, in order to get this kind of exposure. You
15 can see that there are light spots. These continually
16 move across the forest floor so that posies at the ground
17 level get a bit of light, but only for short periods
18 of time. The ground cover includes the dwarf dogwood
19 and the solid cover then of mosses.

20 I mentioned earlier on, that
21 in many of these forest communities there can be a
22 solid cover of mosses and this illustrates it. There
23 are certain ones that are restricted in these habitats.
24 Many plant ecologists will name a community on the
25 basis of the dominant forestry, maybe an understory
26 shrub and then a dominant moss layer; there's a
27 procedure that's been worked out, used in Europe and
28 in North America.

29 Moving onto the northern
30 portion now of the closed Boreal Forest near Norman

L.C. Bliss
In Chief

1 Wells. The winter road shows up through here, and the
2 main reason I included this slide is to demonstrate,
3 to illustrate the patchiness that you see, the result
4 of past fires. As one flies over an area, this is
5 one of the things that always strikes a person. The
6 commonness of the abundance.

7 Lowland area then, that is
8 tree growth along the gravel raised edges of these
9 lakes, so that white spruce may occur down here. Much
10 of this is black spruce, as well as white on the slope,
11 but down in the low and boggy areas here where the soils
12 are cold, more acid, it's primarily black spruce. Some
13 areas then of sedge fens show up here, lakes filling
14 in, plant succession occurring for two reasons:
15 Primary succession here in the sense of a lake being
16 covered over with vegetation in time;
17 Secondary so-called succession here following fire,
18 meaning that there were not plants previously growing
19 here, so this is a primary process and becoming
20 occupied by plants; a secondary process here in the
21 sense that plants were there before and are re-growing.

22 Looking straight down then,
23 in that same general area you can get an appreciation
24 here then for the amount of sedge fen and bog, black
25 spruce that can occur in the area. Very poorly drained
26 land, holding a tremendous amount of water again.
27 Dr. Church was talking about this yesterday. With some
28 rains -- and many times there is not the immediate
29 re-charge back in or release of water, back into the
30 river system, stream system because a landscape of

L.C. Bliss
In Chief

1 this kind can hold so much moisture, it moves out
2 slowly, as opposed to other areas with less vegetation,
3 different kinds of soil characteristics where the
4 run-off is much more rapid.

5 A better view looking straight
6 down of the sedge fen with scattered tamarack, a species
7 that I have not referred to before, a tree which typi-
8 cally grows again in more neutral soil, the black
9 spruce in more acid soil. Raised areas here with a
10 combination of black spruce and larch, but again you
11 can see this tremendous mosaic pattern. There's enough
12 lichen on the forest floor here that you can see a
13 light color of lichen and we'll see this more dramatica-
14 lly as we go further north into the forest tundra.
15 We're still dealing within the Boreal Forest segment.

16 Down on the ground then, this
17 is a sedge fen. Some cattails but primarily sedges which
18 are grasslike plants, a fairly solid covering yet it is a
19 pretty soupy situation as well, grading back then to
20 a shrub zone and into a forest then of larch and
21 spruce beyond.

22 On the other hand, a situation
23 that's a bit more on the direction of a bog, there is
24 still some larch around but it's primarily black spruce,
25 and a ground cover now of the sphagnum moss and a
26 greater amount of shrub cover. The ground cover then
27 shows a little better here, and it will show in the
28 next slide. Here is an area of pretty good growth of
29 black spruce, the trees may be 150 years old, but
30 they are probably 50-60 feet in height, which is pretty

L.C. Bliss
In Chief

1 good growth for a spruce in a situation such as this;
2 it doesn't happen very often. Down at the ground
3 level then, the Labrador tea, this thing with a needle-
4 like leaves, new shoots are just beginning to emerge
5 in the spring of the year, little cluster of flowers
6 and the mass of mosses, some of which include a bit
7 of sphagnum, so that this is more typical then of a
8 true bog than a true fen situation.

9 We're now near the northern
10 limit of the closed forest, an expanse of black spruce
11 in the Norman Wells area, trees that are only about
12 30 to 40 feet in height, and are probably a couple of
13 hundred years old. They don't grow very fast. The
14 ground cover is largely low shrubs that show up here
15 in the spring of the year, including a fair amount of
16 lichen. But slow rates of tree growth; following
17 fire, spruce comes back in very rapidly, there's a
18 tremendous amount of seed available, usually in these
19 situations, it germinates rapidly and produces a very
20 dense stand, so one of the problems of course in a
21 burnt-over area is that the trees come back in too
22 abundantly, too many trees further slows down the
23 growth rate because there is not that much in the way
24 of nutrient material for each individual one. This
25 is what forestry is largely based upon, density, numbers
26 of individuals per unit area, so that in a burn
27 such as this then it can frequently further deteriorate
28 the situation if the stand is this dense.

29 On the other hand there may
30 not be numerous but there are several more recent

L.C. Bliss
In Chief

1 studies which show that once we get into this kind of
2 a situation where there is discontinuous permafrost
3 and the possibility of permafrost in areas, that a fire
4 will tend -- let's start off another way. -- that in
5 a mature stable forest, with a lot of canopy cover and
6 ground cover, if there is permafrost, the active
7 layer will be relatively shallow, only a foot or so.
8 Poorly drained, cold soils. The trees will stagnate
9 under these kinds of conditions.

10 On the other hand, if a fire
11 burns through the area, this then opens up the situa-
12 tion to more radiation, there will be an increase in
13 the active layer for a number of years, and the re-
14 growth of trees on that site will actually be more
15 rapid, so that there is some indication in some areas
16 that fire may not be that detrimental, if we can hold
17 down the numbers of units -- trees per unit area:

18 that come back in -- that actually by having a deeper
19 active /layer there will be an increased rate of plant growth,
20 some of the organic matter in the acid materials have
21 been released and that actually there is some rejuv-
22 enation. All I'm really saying is that we still
23 don't have enough information on some of these kinds
24 of things to know precisely which way to go in a
25 management scheme. It used to be that fire was always
26 thought of as being a very detrimental phenomenon for
27 all systems. We now know that that is not always the
28 case, that there are many kinds of vegetation that
29 are quite dependent upon fire, and that the rejuvenat-
30 ing and regrowth of trees in some cases may actually

L.C. Bliss
In Chief

1 be stimulated as a result of it, when we begin
2 thinking about all the other attributes.

3 Merely to demonstrate that
4 it's not just a forest of trees, there are also animals.
5 Red squirrels can be quite abundant, and this is a nice
6 cache of cones, squirrel colony.

7 Soils, just very briefly tend
8 to be quite acid under these kinds of forest of
9 spruce, so much so that the organic material and much
10 of the fine soil material is removed actually from the
11 upper portion, the upper horizon, what we call the
12 A horizon, and deposited down in the B horizon. So
13 whenever one finds, except where there's been fire and
14 there is an ash layer, whenever one findsⁱⁿ a coniferous
15 forest a light-colored soil such as this, it's an
16 indication that the soils are quite acid and relatively
17 poor growth for many kinds of plants. May we have
18 that off for a minute, please?

19
20
21
22
23
24
25
26
27
28
29
30

1 Let us now turn from the
2 closed forest to the open forest, the forest tundra,
3 and again repeat this process of getting some idea
4 of, again along the route in this case from Norman Wells
5 to Travaillant Lake area, south of Inuvik, a hundred
6 miles roughly.

7 In this particular area then
8 there is a considerable amount, although on a percentage
9 basis it does not appear that much, of both fen, wet
10 sedgy situations as well as open water. There is still
11 a considerable amount of river bank with shrub and
12 tree complex. There is a wee bit of mixed woods in
13 this area. There is a real increase than in the number
14 of -- or the amount of the land that has been relatively
15 recently burned, fires are important, and again, about
16 half of the landscape which is in relatively mature
17 open forest. In terms of what does the landscape look
18 like then, in relation to topography and where do these
19 different things grow, idealized it may look something
20 like this. Where on ridge tops, if it is well enough
21 drained and the like and exposed enough, we may actually
22 have no trees at all and it may be in essence a shrub
23 tundra or cushion plant. Well drained soil and an
24 active layer that is quite deep. Roughly a meter.

25 On the slopes where it is a
26 bit warmer, we may have white spruce and birch occur-
27 ring, the best drained areas, the best microsite will
28 still get some of these, what we might call better
29 site species occurring. But much of the land then
30 will be very open black spruce with scattered shrubs

1 and mosses, very poorly drained soils, acid soils and
2 a thinner active layer.

3 Along streams there will be
4 a zone of shrub and there may well be taller black
5 spruce growing, even some white spruce, again because
6 there may well be gravels, sands, better drainage,
7 warmer situation again and therefore a shift. Better
8 tree growth and even in some cases a shift to white
9 spruce from black. Finally then, areas of sedge fen,
10 very little in the way of tree growth, acid soils to
11 neutral soils, but more towards the neutral side of
12 things, but a relatively low nutrient status. In
13 fact most of these have a low nutrient status, save for
14 there is
15 this situation where/this annual flooding and bringing
16 in of new fine material and to some extent on these
17 slopes here where there is better decomposition, better
18 processes going on.

19 May I have that back again
20 then please. Let's look from the air and then go to
21 the ground. We are now in the forest tundra, the
22 south arctic. Scattered trees. Large areas of lichen
23 mat with essentially no trees as showing up here and
24 up above. The vast areas then of open forest, the
25 lichen cover in this case showing up through, giving
26 you this light pattern. Trees then again being a bit
27 denser along with shrubs along the drainages. You
28 can see that here. You can see a ridge top here and
29 one over here, again that is darker in colour because
30 of more trees closer together. Better growth.
So that even from 20,000 feet one can get some

1 impression of what is where and if one knows a little
2 bit as to why they are there. But let's go to the
3 ground.

4 Open spruce, lichen woodland.
5 Important winter habitat for caribou. One of the
6 things that we again do not fully understand is the
7 role of fire in the winter life of caribou, in the
8 sense that we know that lichen play an important
9 diet component of the winter diet of many populations
10 of caribou. If a fire burns through a forest
11 that
12 such as this / takes 50 to 100 years for the lichen
13 to come back, does that effectively eliminate the
14 caribou. I am sure that Mr. Jakinchuk will talk
15 much more about this, but I wanted to
16 introduce it here in terms of this kind of a forest
17 situation. But an open grown forest, growing on
18 down slope into a different kind of situation.

19 Sandy soils, good
20 drained site. Down that slope, out into a flat
21 land, still scattered spruce, even more stunted
22 in its growth, a shallower active layer, soils more
23 acid, but lots of other things now growing in the
24 under storey. Little low shrubs and grasses and sedges.
25 But very limited in terms of the tree growth.

26 This is going north, that
27 was about 30 miles south of Inuvik. Now we are going
28 about 30 - 35 miles north of Inuvik into the foot-
29 hills, or into the slopes of the Caribou Hills there.
30 A south exposure with white spruce, a north exposure
with essentially no trees, or if there are, a little

1 bit of black spruce, so that even in one little
2 valley system, we now begin to get enough differences
3 in slope exposure, soil temperatures, depth of the
4 active layer, influencing more intimately than what
5 occurs where. Better cover of plants here, a thinner
6 cover of vegetation here and go to the ridge top as
7 we will in the next slide and out, in essence, into
8 the tundra.

9 Black spruce coming up along
10 the slope here, very stunted trees, and then bang,
11 we are out into the shrub tundra. Very dramatic in
12 terms of topography, snow cover, temperature regime
13 influencing again what grows where.

14 Going east of Inuvik, 35 miles,
15 a river valley system with relatively dense black
16 spruce in the background, again grading out into the
17 edge of the tundra treeless areas with a few last
18 scattered clumps of trees. Trees we have not cored,
19 but I will be willing to guess are at least
20 80 to 100 or more years old. They grow very slowly,
21 even though those trees are only about eight feet in
22 height, they have been there a long time. They are
23 barely hanging on. I did not include a slide, but I
24 have some that show that out two hundred feet from
25 this particular spot, black spruce was not growing
26 as an upright tree, it was crawling along the ground
27 in and around the soil structured patterned
28 ground. So this is at its limit.

29 On the other hand, go back
30 to Inuvik on the warm slopes -- birch. Paper birch.

1 One can pretty well predict at this northern limit
2 of where one finds birch, that wherever it occurs
3 there will either be gravels near the surface or bed-
4 rock fairly close to the surface. There is a
5 deeper thaw, the soils are warmer, it is a more
6 nutrient rich environment, otherwise you would not
7 have this tree growing there. It looks much more
8 like this area or even several hundred miles further
9 south.

10 Fire in the forest tundra.

11 This has been referred to several times, I merely
12 wanted to go through a little bit of this again in
13 terms of plant succession. The 1968 Inuvik fire,
14 this is three years later. Some of the shrubs survived
15 along the drainages, but essentially none of the
16 trees. There was a mixture of birch and spruce in the
17 upland. It is essentially pretty well covered landscape
18 then of grasses, sedges, and in some cases fireweed.
19 And there is the fireweed. Very easy to see where the
20 fire burned and did not.

21 Open grown spruce, birch,
22 back up on to the slope, fireweed comes in very rapidly,
23 it produces a lot of seed, the seed blows around
24 readily, it germinates easily. So two or three years
25 after a fire, if there has been any population of
26 fireweed in the area, it will come in very abundantly,
27 to produce such an amount of cover.

28 In other areas though, that
29 is in an upland area, and in time then, I should say
30 before I go on to the other point, in time the fire

1 weed will be replaced by an under storey of shrubs
2 and eventually black spruce will begin to regrow as
3 we can see it here. This is a burn that is about
4 30 years old, 20 to 30.

5 Slides, of course, mud slides
6 can occur in areas such as this. This shows again
7 the shrubs that survive, a combination of lots of
8 grasses on the ground, the soil polygon development
9 here on the surface of this mud flow, but the fact
10 again that I wanted to demonstrate here is not that
11 slides occur, they obviously do, but ^{the} that plants
12 will come back in on them relatively rapidly following
13 this.

14 This is down on the ground in
15 the same general area and here is again our friend
16 the fireweed along with grasses.

17 In lowland situations, a mile
18 or so from that previous picture though, it was
19 originally scattered black spruce without any
20 birch. Soil Polygon patterns with cotton grass and
21 an under storey of shrubs that are much more typical
22 out into the tundra, that is why this is called
23 forest tundra. That is one year after the fire.
24 This is '69, these plants have survived and yet
25 two years later, that same site looked like this.
26 Which again, the reason for showing this is the
27 rate at which plants, if given a chance, in this case
28 they are native to these areas, they have either
29 in, in this case they have regrown from
30 old root stocks, but if stuff remains there, it will

L.C. Bliss
In Chief

1 come back relatively fast. Again, as Dr. McKay
2 pointed out yesterday morning, the soils are warmer,
3 the active layer becomes deeper after a fire, more
4 nutrient uptakes so that the plants that survived the
5 darn thing have actually got a better environment
6 now to grow in for a number of years and their growth
7 is quite rapid.

8 200 feet away, in an adjacent
9 area that had not burned to show the contrast. Go
10 down into the valley and my goodness, we have got big
11 white spruce again. Warm river system, nutrient
12 enrichment, warmer soils, deeper active layer, resulting
13 then, in a channel such as this, with little low
14 herbaceous plants and horsetails coming in along the
15 bare sandy, silty, soil surface, grading back through
16 shrubs, big broad expanse such as here, or in here,
17 and finally into forest. But again, over time, over
18 a hundred years or so, 200 years, as this white spruce
19 becomes a dense forest stand, the permafrost table rises,
20 the environment becomes less conducive to spruce, so it
21 actually slows down in its growth rate, the forest
22 stand may open up and there actually may be some re-
23 cycling of that kind of sequence. There have been
24 studies in the North done especially with regard to
25 black spruce which show that.

26 So that again this business of
27 change, the vegetation modifying the environment,
28 changing the soil situation, making it less conducive
29 to itself and more to other things is part of the
30 biological situation.

L.C. Bliss
In Chief

1 Before we go to that I want
2 to very briefly summarize a little bit of the
3 information then with regard to tree growth and the'
4 like if we could have that one off please and a
5 couple of these other things.

6 I mentioned on several
7 occasions the business of reduced tree growth as we
8 go north and this hopefully will demonstrate this
9 very well.

10 How high will trees grow on
11 the average in one hundred years? In the boreal forest
12 in the southern portion, essentially in the Fort
13 Simpson area, white spruce along rivers will be 60
14 to 70 feet high. Jack Pine and spruce in upland
15 areas about the same. But black-spruce in
16 lowland situations throughout the area, you see only
17 putting on half as much heighth growth in a
18 hundred years.

L.C. Bliss
In Chief

Poor environment, cold more
acid soils, less nutrients.

Move then to the forest
tundra and a tremendous reduction in relation to these
others. Black spruce, I should say open rather than
aspen, it's a typographical error, open black spruce
with moss only 20 to 30 feet in 100 years, or in the
areas with lichen cover, only 15 to 25 years, I'm sorry
15 to 25 feet in 100 years. So that tree growth is
greatly suppressed, and yet even as far north as Inuvik,
moving on into the valley, along the river one is able
-- many people are able to harvest white spruce that
does grow quite rapidly in that specialized kind of
situation.

Now we've talked a lot about
fire, let's summarize a wee bit of this in terms of
fire rating, 5 being a high rating, 1 being a very low.
Within the forest tundra, amazingly enough, and
part of the closed forest, fire susceptibility is
the greatest. In terms of spruce or spruce, aspen and
pine forest, ^{white} there's a lot of material there's always
a lot of litter; over time these are very susceptible.
That even occurs then as far north as the forest tundra
of some areas of open spruce.

On the other hand, in much of
the area, in Alberta and up to Fort Simpson, spruce
stands are somewhat less susceptible and this grades off
then into the tundra where a few years ago people didn't
really think fire occurred very much -- it probably
doesn't but nonetheless there are some fires -- there's

L.C. Bliss
In Chief

1 a lot of Russian literature which shows that much of
2 the shrub tundra is actually converted former forest
3 tundra because of the rapidity of fires over the years.
4 So we have a fair amount still to learn about fire
5 ecology in the north, but in general, because of the
6 growth rates of plants and the amount of stuff that's
7 there, there's much less potential for fire, it's
8 less severe in the tundra than it is in forested
9 areas.

10 A little bit of data put in
11 together shows that if blocks along the route of
12 40 x 80 miles are laid out, and one goes back to the
13 records to determine the number of fires in essence in
14 the last ten years, that in all of these areas there
15 are a reasonable number of fires, even except out
16 along the coastal plain in the Arctic tundra, that
17 there had been lots of areas that had burned off as
18 much as up to 28% in some areas, but much of it, as
19 you see, less than 5%; and that the average sized fire
20 is relatively large in some of these areas, especially
21 in the northern portion. So that even the forest
22 tundra has a considerable amount of fire, and fires that
23 have occurred there have tended to be larger ones.
24 That's really the message.

25 Finally in terms of this,
26 that a considerable amount of land does burn off in
27 every ten-year period, there is incomplete data here
28 simply because fire records weren't taken that far back
29 and it's fairly consistent by 10-year groups. You see
30 here we have only three years of data, and yet there

L.C. Bliss
In Chief

1 is over two million acres that burned in the last,
2 in relation to six million over the previous ten.
3 That same patterning shows up here, so that fire --
4 fires are characteristic of the north. They tend to
5 be steered in the direction of a few large fires. There
6 are many smaller fires. There are some forest ecologists
7 that would argue that one might be better off not to
8 fight as many of the fires as we do in terms of the
9 amount of money that is spent and the like, and yet
10 there are others that would say that is clearly not
11 the case. I only raise it to illustrate again that
12 we haven't advanced stories enough in some of these
13 areas to have as much information as we might like.
14 Yes?

15 THE COMMISSIONER : Dr.

16 Bliss, excuse me, is the incidence of fires in the
17 Mackenzie Valley, especially in those areas where it
18 is greatest, is there greater incidence of fires than
19 say there would be in the coniferous forests of the
20 Pacific Coast, or the spruce forests of the Northern
21 Interior of British Columbia?

22 A No, I don't think so
23 but that's sort of off the top of my head. I don't
24 have -- I can't think back to concrete solid data
25 to properly answer you, sir, but I would say in
26 general, no. Many of these start as a result of
27 lightening storms and summer storms in that area, are
28 fairly frequent, so that I think in the overall that the
29 fire frequency probably is no greater there, or that
30 much different. That was one of the reasons for

L.C. Bliss
In Chief

1 including the data from Alaska, from another huge
2 large area where these have been studied to show that
3 it's pretty much the same all over, and we're beginning,
4 at least ecologically to take somewhat a different
5 view in the interpretation of fire and the role that
6 it plays in nature than we did 20 years ago, or 30.
7 This is a little bit of pedantic information in terms
8 of the shift that occurs as we go north from closed
9 forests of pine or spruce, fir, or this open black
10 spruce, into very open black spruce, with the kinds of
11 plants that occur, the height of this refers to the
12 massive amount of stuff in relation to time; and the
13 main thing that I wanted to point out was that
14 merely again it takes a lot of time for equilibrium.
15 Roughly 100 to 200 years for many of these things to
16 come back in; but the lichens are slow to come back
17 in, they may start in 25 to 50 years but they frequently
18 don't build up their populations until around 75 to
19 100 years. Mosses come back in more rapidly. Of
20 course the shrubs, the tall shrubs and the low ones
21 come in quite rapidly; some of the trees, depending
22 on the kinds, come in rapidly, but again some of them
23 taper off. Here is this business of birch, not being
24 shade tolerant, going out as black spruce increases.
25 It can't grow in the shade of the spruce, so the long-
26 term thing then is, a situation with lots of black spruce,
27 relatively little in the way of low shrubs, but lots
28 of mosses and some lichen. That's the message.

29 Let's now turn to the last
30 unit, the Arctic. Ridgetops, upland areas, exposed

L.C. Bliss
In Chief

1 relatively little snow cover, cushion plants. Poorly
2 developed soils, good drainage, deeper active layer.
3 Soils tend to be a little bit more neutral. There is
4 less peat accumulation. On the gentle slopes we tend to
5 find low shrubs, shrubs a foot and a half, two feet
6 at the most in height. Along lower slopes, more
7 poorly drained areas, we tend to find what is really
8 a group of sedges but they're called cotton grass,
9 with associated heath species. These are poorly drained
10 or imperfectly drained areas, down along streams, as
11 we saw further south in the forest, shrubs occur. With
12 better drainage there's warm water, a deeper active
13 layer, more nutrients, it's better for growth. In turn
14 in the winter-time this area is covered more deeply with
15 snow and in many of these northern areas plants will
16 grow to a height comparable to winter snow cover.
17 That's an important inter-action, and then many poorly
18 drained wet areas of wet sedgeland.

19 I don't have, unfortunately,
20 a map or a sheet here that will illustrate the per-
21 centage of lands, we haven't been able to really
22 calculate that out as well as we would like.

23 As we move out into the
24 tundra then we still find spruce, in this case white
25 spruce, along these lowlands, drainage areas or in
26 this case river terraced, stream terraced. Where there
27 is coarser texture sands and gravel, they tend to
28 thaw more deeply in the summer, they are lower in
29 elevation so there is more snow cover in the winter,
30 there is better protection and trees will still grow

L.C. Bliss
In Chief

1 out into the tundra in such areas.

2 But the bulk of the land from
3 the air looks like this, with low shrub tundra complex
4 on rolling hills, the lowland areas then of sedge
5 tundra, raise centre polygons. The tops of these
6 are much drier, they are mainly cushion plants and
7 lichens and we will see details of this as we go on.
8 But one of the important things is the landscape is
9 really totally covered with plants.

10 A lake that is filled in --
11 Dr. McKay talked about this yesterday in the develop-
12 ment of pingos -- well-drained outer core, even though
13 it's solid ice in the centre, what soil is there is
14 warm and relatively dry and tall shrubs will grow
15 up on it, as opposed to lower shrubs around the edge
16 of it, the lake then that is filling in is a sedge
17 marshy area, dramatized with fall coloration. So that
18 again one can read the landscape quite well at certain
19 times of the year.

20 Out along one of the streams
21 then, still a little bit in the way of spruce but a
22 real complex of shrubs along the drainage -- tall shrubs
23 that is, with shorter shrubs in the rolling upland
24 area. The lighter colored areas that you see
25 scattered through here are areas of cotton grass.

26 Down on river grave~~s~~ these
27 plants get started, there are shrubs as well as herba-
28 ceous plants, high level of nutrients, relatively warm,
29 well drained soils. Over time it may become a closed
30 vegetation such as this. In the summertime this is

L.C. Bliss
In Chief

1 important habitat for moose, to the limited extent
2 they will even remain in some of these areas for
3 protection in the wintertime. But a tremendous lush
4 development, it's really the banana belt of the Arctic
5 in the sense of a beautiful display of flowers, lush
6 vegetation, a typical from that standpoint.

7 Confined then to the river
8 valleys and along drainage areas, slopes down to lakes
9 such as this, again this is covered with snow in the
10 wintertime, it's not all melted off, and again you can
11 get some appreciation for the fact of the relationship
12 of topography, snow cover, and in essence the height,
13 the mass of vegetation that occurs.

14 In the rolling uplands,
15 though, it's this low shrub tundra with the pingo in
16 the background, a complex of dwarf birch, scattered
17 willows, and lots of other things mixed in. Very good
18 grazing ground in the summertime for both caribou
19 and reindeer, the important habitat for ptarmigan and
20 other birds. Good habitat for lemming, and the ptar-
21 migan in one of these upland shrub situations.

22 Ridgetop areas may have these
23 low cushion plants, Dryas being one of them.
24 Soils are warmer, drier, it's easier for burrowing
25 animals and there's the ground squirrel, even as botan-
26 ists we are interested in these inter-actions.

27 Lower slopes more poorly
28 drained, shrubs in the upland area, cotton grass now
29 in this intermittently drained area down slope. Cotton
30 grass named in the sense that as the seeds mature

L.C. Bliss
In Chief

1 there are cotton masses to these, they carry them away
2 sort of like dandelions seed, and are very showy in
3 late June, early July as the seed matures. Soils
4 in these areas are very poorly developed, they develop
5 under low oxygen regime, and therefore rather than
6 having the bright brownish reddish color, have these
7 blues and greys, which indicate that rather than
8 oxidation it's actually a reduction process, stuff
9 going on minus oxygen biologically.

10 Down then further slope, we
11 were back in cotton grass tussock stuff here a few
12 minutes ago, now we're down in the wet sedge component
13 with deep peat at the base. Again shrubs on the slope,
14 so again you can see how topography, drainage, differ-
15 ent kinds of soils interact then in these different
16 kinds of assemblages of plants.

17 You raise centre polygons
18 again from the air, showing shrub complexes here,
19 the ice -- tops of the ice wedges in this case have
20 not melted off sufficiently to show surface water, but
21 the centres of these are much drier, better drained
22 than are the edges. If we go down on the ground into
23 that kind of a situation, a slightly different one
24 that in the sense here the tops of the ice wedges
25 have melted out in the summer, a wet environment so that
26 we get wet sedges here and yet on the top where this
27 man is standing, only low cushiony plants.

28 Microtopography being very
29 fundamental in terms again of what will grow where. This
30 also plays a key role, as others will talk about, in

L.C. Bliss
In Chief

1 terms of small mammals.

2 We talk about heath shrubs,
3 this is a close up looking down onto the ground
4 with these little low shrubs. Some of these may be
5 30, 50, 80 years old and yet they're only a matter of
6 a few inches to a foot or so in height. A complete
7 cover on the ground then of lichens and moss. Perma-
8 frost, the active layer, is only about a foot in
9 depth. Here there are coarse gravels underneath.
10 How do I know? Because there's a solid cover of lichens,
11 it means good drainage. Actually we scraped the sur-
12 face and yes, there were. It's near the edge of a
13 lake, it's an old beach. Plants can be used -- not
14 always, it's not foolproof -- but in many situations
15 the kinds of plants can be very strong clues as to
16 sub-strata situations.

Lakeshore edges, just as in more tempered regions with plants that grow in the water, plants that grow out on to the marshy area and upland shrubs. Same kinds of sequences we are all familiar with from the southern part of the country. What goes ^{on} along the major rivers then, in terms of fine materials that are deposited with sedges out in this area, medium height shrubs here, an area that is a little bit better drained here with taller shrubs and in this case in the fall of the year, they still have a dark green colour. This is literally alder, mass, willows and low sedges, rolling upland beyond with other things.

The sedge areas are very important, especially in the fall feeding of snow geese as they come off of the Arctic Islands, especially Bank's Island. Feed in areas such as this before they move south, again Dr. Livingston will be going into more detail and I want to begin to weave a message in terms of these interactions of what is important and where are they found. Rolling upland area then, with more shrubs.

Lowland situation with raised centre polygons, rims and the centers of these are depressed, I should have said a depressed centre, not a raised centre. A depressed centre with a raised rim, a little bit dry around the periphery and more shrubs, wet sedges in the centre, so again on a micro scale basis, one can see a tremendous difference in what occurs where. As one

1 goes north then and west this is looking across the
2 north slope in the Yukon, massive ice melting out
3 right along the edge of the coast. Huge lowland area
4 of wet sedge into tussock tundra back towards the
5 mountains and then back into alpine conditions there.

6 Further north, this is actually
7 into Alaska, it shows a pattern of an old lake, drained
8 out, in part -- or filled in at least with vegetation,
9 with a grass that grows in the shallow water turning
10 a brilliant colour in the fall of the year, this is
11 open waters, the blue. Sedges then around that and
12 in very wet areas, the raised beach of the lake
13 with taller shrubs and again depressed centre polygons
14 with the raised rims and the shrubs growing around the
15 edges of those. Important habitat again in the summer
16 time for caribou. Down on the ground this is what it
17 looks like. It is wet everywhere and yet it looks
18 to the eye in a picture like that as if it is a
19 pretty dry landscape.

20 Cotton grass complexes, this
21 upland area grading down then into the stream bottom
22 with its mass of willow. Again those bottom land
23 areas being very important for moose in many areas
24 and there is an upside down moose, sorry about that.

25 We are really not down under .

26 Finally up in the general
27 area then of Prudhoe Bay where there are large rivers
28 again coming out with coarse gravel and this wet, wet
29 landscape of sedge with lots of thaw lakes.

30 Finally, moving back through

L.C. Bliss
In Chief

1 the mountains into alpine tundra, here is really a
2 mass of treeless landscape and yet many of these
3 valley situations will have trees in as we will see
4 as we go to the next.

5 Trees in the valley of
6 black spruce, going up through a zone of shrubs and
7 then into other things above that.

8 Moving up the slope in a more
9 open forest where the active layer is quite shallow
10 it looks like the forest tundra that we saw in the
11 valleys on back to the east in this case -- this is
12 back in the Yukon. Open ground forest with shrub
13 under storey. Moving on up slope then into
14 just the shrubs, tall willows and birches again im-
15 portant summer grazing ground for some mammals and
16 then finally further up slope in broad bench areas,
17 cotton grass complex, it looks just like the arctic
18 we saw before around Tuk, but now we are up in eleva-
19 tion in the mountains and finally higher up into
20 cushion plant vegetation. Again, quite important
21 habitat for numerous species of wildlife, and there
22 are some of them.

23 Dense concentrations in
24 the summer time at times fading in some of these
25 high alpine areas where they are getting a considerable
26 amount of sedge, grass, some lichens.

27 It shows that the plant
28 cover is short and yet there is sufficient forage
29 there for them to continually move on and get some
30 fens.

L.C. Bliss
in Chief

1 I wanted to again come back to
2 this business of permafrost meld out and plant stability.
3 This is that same big complex that Dr. McKay was looking
4 at but now let's look at it biologically from the
5 standpoint that okay, here is an area that melded out,
6 I do not know how many years ago, but it has become
7 restabilized by plants, so the plants do move
8 back in on these slide areas. There is an old
9 slide there that is completely revegetated and then
10 down on the ground again -- we are upside down --
11 but a solid mass of grass and shrubs -- probably about
12 30 years after the slide had stabilized.

13 Last view -- a few
14 pictures of plants. The cranberry, Mountain Cranberry,
15 which in the European, especially the Scandinavian
16 countries is made into a jam which you can sometimes
17 buy in the stores here as Lingonberry. Little
18 cranberries.

19 Little rhododendron that
20 grows up as far as Inuvik, very colourful little
21 shrub characteristic of the low arctic and on into
22 alpine areas and finally the cloudberry which we
23 do not make again as much use of as do some of the
24 Scandinavian people, it is a very good delicacy in
25 their diet in many cases.

26 The last one that I want
27 to show is switching the topic just a wee bit to
28 conservation. So far we have been getting an idea
29 of what occurs where. Now, I want to spend just
30 a couple of minutes again back because of my interest

L.C. Bliss
In Chief

1 in the International Biological Programme.

2 This refers to the Canadian Committee of the I.B.P.,
3 conservation of terrestrial areas is the C.T.

4 A Committee has worked on
5 the establishment of the possibility of setting aside
6 areas in the north. As I am sure you are aware, there
7 is a large tract of land in northeastern Alaska
8 that has been set aside as a wildlife range and the
9 desire of many people to have something comparable
10 to that in the Yukon.

11 Again related back to
12 caribou, to huge landscapes that are necessary because
13 of this as well as some of the general patterns of
14 vegetation that occur as well as several other sites
15 that occur then on down to the 60th parallel that
16 there are areas along here that are either relatively
17 unique or in many cases really characteristic and
18 the feeling being that if we are going to set aside
19 areas in the North we need to begin to push on this
20 sort of thing now just as people had the foresight
21 to set up National Parks, Provincial parks in the past,
22 we need to begin to think now more intensively in terms
23 of the possibility of setting aside similar tracts
24 of land that illustrate nature in its complexity in
25 the north.

26 In summary then, we can
27 have the lights back on, I would merely like to
28 comment very briefly that these northern lands, both
29 forest and forest tundra, are biologically very
30 diverse. They are relatively low in terms of the

1 density of plant and animals except in a few localized
2 areas especially along the delta area.

3 In general, biological pro-
4 ductivity is quite low in these northern lands. We
5 have seen some areas of spruce forest that are
6 very lush, but in general both plant growth as well
7 as animal growth is reasonably at a low level. It is
8 no accident that many of the native people live along
9 water courses of lakes or rivers so that they can
10 harvest both fish from the water as well as some
11 wildlife from the land.

12 In the coniferous forest areas
13 wildlife numbers are relatively low. This is true out
14 into the tundra even though there are these large
15 concentrations of caribou in the summer time.

16 Basically the environment is
17 well adapted to disturbance. We see this through
18 fire. We see this through slumps that have occurred
19 over permafrost in the past. The fact that there
20 are a group of plants always in these northern systems
21 that come back in to these areas. One of our desires of
22 course, as ecologists, is to sort this of what is
23 adapted, what can be utilized by people in terms of
24 this again to aid nature.

25 I feel that we do need
26 to preserve some of these northern landscapes, to
27 set them aside for future generations and finally
28 the one thing that I have tried to give us some
29 impression of this morning, although we have
30 concentrated on the vegetation, is the fact that there

1 are tremendous interactions of plants, of animals,
2 of land surfaces, drainage, soils, it is all
3 interwoven into packages that we sometimes talk about .
4 in terms of ecosystems and in fact at times have
5 studied as ecosystems. Thank you.

6 THE COMMISSIONER: Thank you,
7 Dr. Bliss. It has been a privilege to listen to you.

8 MR. SCOTT: Mr. Commissioner,
9 so a change can be made, can we take a 15 minute
10 adjournment?

11 THE COMMISSIONER: Yes, we
12 will adjourn for 15 minutes.

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

MR. SCOTT: Mr. Commissioner,
the next witness is R.D. Jakinchuk.

RONALD D. JAKINCHUK, Sworn:

THE SECRETARY: Will you
state your full name, please?

A Ronald D. Jakinchuk

DIRECT EXAMINATION BY MR. SCOTT:

Q Mr. Jakinchuk, you are
at present the president of Renewable Resources Con-
sulting Services Limited, is that correct?

A That's correct.

Q And how long have you
been associated with that firm?

A Seven years.

Q I understand that you're
a graduate with a B.Sc. at the University of British
Columbia.

A I'm a graduate from the
University of British Columbia, with a B.A.

Q I'm sorry.

A With a major in zoology.

Q I see, and since gradua-
tion what work have you done?

A Since graduation I've
been involved in both government service as well as
private consulting. Initially I worked for a short
period with the Entomology Research Division of the
Department of Agriculture,

Q What is entomology?

R.D. Jakinchuk
In Chief

1 A The study of insects.

2 Q Yes.

3 A In 1964, subsequent to
4 that, I was engaged in contract work with the Department
5 of Forestry -- Federal Department of Forestry dealing
6 with land classification for wildlife. Subsequent to
7 that I was engaged in various positions with the
8 Canadian Wildlife Service in classifying habitat for
9 waterfowl and ungulates under the Canada Land Inventory.
10 Following that period I started the consulting firm
11 Renewable Resources.

12 Q I see. Well now, have
13 you done any field research or field work in the Arctic
14 or sub-Arctic?

15 A I have not been engaged
16 in long periods of direct field research in the Arctic.
17 I have been engaged in surveys, in periodic inspections,
18 in both Alaska and Canada, in ground work in the Arctic
19 associated with some of the research I'll be reporting
20 on; but I have not spent long periods, my role is
21 more of an inspection and direction one rather than
22 having spent long periods of time.

23 Q Yes, and just for the
24 record, have you latterly done some work for the applicant,
25 Arctic Gas?

26 A Yes, I have -- my company
27 has been engaged as consultants to Arctic Gas and its
28 predecessors since 1971.

29 Q Yes, and generally in
30 what field?

R.D. Jakinchuk
In Chief

1 A In the field of mammal
2 studies.

3 Q Yes. Would you like to
4 carry on as the other witnesses did?

5 A Thank you. How is the
6 voice? Is this in the right spot?

7 Q I believe it's coming
8 through.

9 A O.K. Well, first
10 something generally about mammals, and I would say that
11 overviews require you to make many generalizations, and
12 I'm quite certain that for every generalization that
13 I make, that someone could cite a specific exception
14 to that. However, this is the task that I have today,
15 and to go from the broad range of what mammals are
16 specifically down to the mammals in the Northern
17 Yukon and Mackenzie Valley.

18 Mammals are an extremely
19 adaptable species, and they're extremely successful
20 throughout the world. I think it's important to note
21 that they occupy quite a wide range of habitat. They
22 live in the ocean. They live in fresh water. They
23 live upon the land. They live underneath the land.
24 Moles, for example, are subterranean mammals. They
25 even fly through the air. The bats have exploited a
26 particular environment that is most normally associated
27 with birds. So that they show a great diversity in
28 their adaptations and radiations.

29 I think some of the reasons
30 that mammals are quite successful as a group are that

R.D. Jakinchuk
In Chief

1 they have various behavioural and physiological
2 mechanisms which enable them to cope with a wide
3 variety of environments. A very important thing, I
4 think, is the fact the higher forms exhibit a high
5 degree of learned behaviour because of the fact that
6 they are subject to quite a long period of parental
7 care, and as a result they learn how to cope with
8 their environment as opposed to those species which are
9 purely instinctive. So much for the generalities
10 on the mammals.

11 Dr. Bliss has very nicely
12 laid a groundwork regarding northern eco-systems and
13 their vegetative components for many of the things
14 which I remark on.

15 My comments will be oriented
16 specifically towards mammals and the populations that
17 are found in the area generally covered by this map.

18 Some of the -- there are
19 some things we can generalize about northern mammals.
20 The factors which govern their distribution and abund-
21 ance, the main things are the primary productivity of
22 their habitat or the lack of it. In the case of the
23 far northern eco-systems it's a very low rate of the
24 primary productivity, that is the capture of energy from
25 the sun by plants, and the transfer of this energy
26 to those animals which feed on plants, and those
27 animals which feed on other animals. The rate of
28 productivity is quite low, and generally distinctive
29 of northern eco-systems.

30 Climatic constraints. The

R.D. Jakinchuk
In Chief

1 climate is very severe. It's not just the cold, it's
2 the snow and the quality of the snow, the depth of the
3 snow, it's hardness, its texture, it's susceptibility
4 to crusting. All of these factors related to climate
5 play a significant role in the distribution and the
6 abundance and the ability of mammals to survive.

7 Geomorphological factors.

8 Yesterday was devoted to some of the descriptions and
9 theories underlying the development of terrain, and
10 terrain characteristics in the north. These same
11 characteristics have an influence on mammals, more so
12 on some species than on others. So all of these things,
13 the primary productivity being low, the climatic
14 constraints and the geomorphology or topography have
15 quite an influence on mammal populations, both whether
16 they exist or to what levels of abundance they can
17 exist. A reflection of this is the diversity of
18 mammal species which occur in the north.

19 For example, in the tundra
20 areas that were described, and I'll just -- if I
21 find my pointer -- in the tundra areas that were
22 described by Dr. Bliss generally here in the lower
23 part of the Mackenzie Delta dipping down over here,
24 there are 24 species of mammals. Now these range all
25 the way from lemmings, very small mouse-like creatures,
26 to caribou and wolves. 24 species. In the Boreal
27 forest described by Dr. Bliss, the number of species
28 increases to 46 or 47, almost double the number of
29 species. If one were to extrapolate into Southern
30 Alberta, the number of mammal species is almost four

R.D. Jakinchuk
In Chief

1 times the number that exist on the tundra, so there
2 is a very definite relationship between the number of
3 species that are supported by more productive southern
4 eco- systems as opposed to those that have less of a
5 productivity and less of a diversity.

6 All natural populations, whe-
7 ther they be ~~micro~~-organisms or whether they be mammals,
8 are limited by their environment and their habitats--
9 food, shelter is required for survival and to maintain
10 populations. In the north, terrain, permafrost, weather
11 play a very significant role not only in the presence
12 of populations but in how mammals have governed them-
13 selves to survive in that environment, to survive and
14 to perpetuate themselves.

R.D. Jakinchuk
In Chief

Other factors that are important in higher organisms are social behaviour. These social behaviours and competition, either competition between the same species for food and shelter, or between different groups of species. I will have some examples in the slides later on that might point out some of this competition. But these are factors which govern once again the population levels.

Something about food chains.

Food chains in the north are generally quite direct, as opposed to more, for example, tropical areas. For mammals, food chains are direct from the carnivores, being at the apex or the peak to the herbivores, the small mammals, the mice, the moles, and the lemming. This directness is reflected in the fact that small mammals, for example lemmings might be fed upon by anything from the size of an Arctic fox to a barren ground grizzly bear, the small mammal being the primary converter of energy from vegetation and the base of the food chain.

Now as a result of these food chains, some mammals ^{exhibit} cyclic fluctuations. I'll get into that a little more briefly, but I was going to say in passing that probably the longest food chains occur in marine environments in the Beaufort Sea. Where carnivorous sea mammals, such as ring seals and beluga whales are at the top of the food chain which starts originally with phytoplankton, phytoplankton being the original converter of solar energy

R.D. Jakinchuk
In Chief

1 in nutrients to a usable form. So that's where the
2 longest food chains are found.

3 THE COMMISSIONER: Excuse
4 me, you threw me off at the last turn there. You
5 said the whales were the top of the food chain.

6 A In a marine environment,
7 they exhibited a longer food chain. You see, the
8 concept of food chains is just to describe who eats
9 whom.

10 Q I understand that, but
11 I wondered who was eating the whale, that's the
12 part that interests me.

13 A Well, in some cases
14 other whales eat whales, but in other cases whales
15 aren't eaten, they just live to a ripe old age.
16 The point is, I think, that one can go very quickly
17 from mice or ground squirrels to grizzly bear, but
18 the length of the relationship in the marine environ-
19 ment goes from the phytoplankton to the zooplankton,
20 it goes on up to small fishes and bigger fishes eat
21 smaller fishes and finally ends up with the dominant
22 carnivore at the top of the food chain.

23 Cyclic fluctuations. All
24 natural free-ranging populations of wildlife fluctuate.
25 They fluctuate from year to year. They fluctuate over
26 longer periods of time. They expand their ranges on
27 some occasions, and their ranges due to environmental
28 factors are contracted at other times. One of the
29 interesting things about northern mammal populations,
30 however, is that some scientists have said that there

R.D. Jakinchuk
In Chief

1 is a periodicity; there is certainly cyclical fluctua-
2 tions that take place in the north. As to whether
3 this is a predictable cycle, however, has not been
4 thoroughly thrashed out in the scientific community.
5 It's been the subject of a lot of research over the
6 last 20 years, research which is still continuing.
7 But it has been postulated that there are four-year
8 cycles in lemmings which in turn is reflected in the
9 number of white fox, Arctic fox, who prey on lemmings
10 to a large extent. It's also been postulated that
11 there is a ten-year cycle in snowshoe rabbits or
12 Bering hare, and there certainly is a fluctuation in
13 numbers, whether it's bang-on predicable at 10-year
14 intervals is a scientific question; and because the
15 lynx is so closely tied to Bering hare, as its main
16 food item, it also exhibits a response in total
17 numbers to the population levels of hare, so that one
18 gets fluctuations in the populations of hare, which are
19 followed by increases or decreased in the population
20 of lynx. Lynx have kind of got them selves in a
21 tight spot because they are so specific to that one
22 prey that they will either prosper or they will crash
23 to low levels, depending on what the rabbits do.
24 Other species which feed on a wider range of prey,
25 as a consequence are more stable. For example, the
26 martin feeds on microtine rodents, once again the
27 mice; but he is able to feed on rabbits, he is able
28 to feed on ptarmigan if they are available, so if one
29 food supply is eliminated, there are options available.
30

R.D. Jakinchuk
In Chief

Options gets me into my next topic, and that is adaptability. One other thing that becomes apparent when one views the mammals of the north, there are a much more limited range of options for them to survive than there are in more complex, more productive, more benign southern habitat in climates. As a consequence, they have adapted to these environmental forces. They have adapted in their form, and how they function. They have adapted in their behaviour, and they have adapted to some extent in their physiology. Their main purpose, if you want to put it that way, is to seek out conditions which are favorable for survival. Now adaptations can include hibernation such as the ground squirrel, which hibernates during the winter period when food supplies are limited, and it's extremely cold, crusted snow. Caribou have adapted by engaging in widespread and dramatic seasonal movements, seeking out those areas which will enable them to survive, and perpetuate. There are physical adaptations such as the hooves of caribou. for example, which are adapted to travel over very wet, boggy terrain, whether it be muskeg or whether it be soft snow, hooves adapted for them to crater out snow in their feeding activities.

Bears go into dormancy, a state similar to hibernation. Moose engage in seasonal movements. All of these behavioural traits and the seasonal distribution reflect the need for the animal or the population to cope with the current state of the environment.

R.D. Jakinchuk
In Chief

1 Now, Dr. Bliss gave us a very
2 good rundown on plant communities. However, I would
3 like to make a distinction between plant communities
and animal habitat, or mammal habitat specifically.

5 That is there is not necessarily
6 a direct correlation between plants or the particular
7 community of forest cover and the animals which occupy
8 it. Habitats represent the sum total of the climate,
9 of the terrain, of the various requirements for shelter
10 and food and reproduction that a mammal requires in
11 order to survive and perpetuate itself. Therefore it's
12 very difficult, often to categorize very glibly and
13 say that this is a caribou habitat and this is not a
14 caribou habitat. As we will see later, caribou
15 habitat encompasses everything from alpine tundra to
16 ice wedge polygon terrain on the north slope. However,
17 the concept of habitat is essentially that area in
18 which an animal frequents in order to meet its needs,
19 and it may encompass quite a variety of plant communi-
20 ties. Now I make this point because later on I'll
21 be commenting on the relative homogeneity of the
22 Mackenzie Valley in terms of mammal habitat, and I
23 don't want to appear contradictory to Dr. Bliss, who
24 has demonstrated by his slides what a variety of plant
25 communities there are.

26 I'd like to comment briefly
27 on the current state of knowledge of mammal populations
28 in the Mackenzie Valley and Northern Yukon. As Dr.
29 Bliss indicated, the last five years has seen a remark-
30 able proliferation of studies of a wide range of

R.D. Jakinchuk
In Chief

1 environmental considerations, and no less for the
2 mammals. Once again, in the initial years of these
3 studies, emphasis was placed on inventories of habitat
4 and inventories of population. These have evolved
5 recently to more sophisticated types of studies
6 relating to disturbance of mammals, disturbance to
7 their habitat as well as their response to various
8 types of human activity and human disturbance. These
9 are important studies. There have been studies ranging
10 in detail from the general to the specific. There have
11 been on some populations, like the very well known now
12 porcupine caribou herd, there has been a great deal of
13 intensive detailed study carried out which includes
14 to some degree the population dynamics of the herd.
15 So there has been -- we certainly know a great deal
16 more now than we did five years ago on the distribution,
17 the abundance, and some of the habitats of mammals in
18 the Northern Yukon, North-east Alaska, and the Macken-
19 zie Valley.

20 However, there are gaps in
21 knowledge that exist in any biological discipline,
22 knowledge is never perfect and I would like to point out
23 that probably in terms of mammals, the areas where
24 information is least available, is in the area of
25 population dynamics and behaviour. It's available for
26 some species but not for others.

I would like now to turn to the northern Yukon and Mackenzie Valley and just briefly describe some of the major habitat components. With the exception of the Mackenzie Delta, which is almost a unique area as deltas go, it is very, very large, very, very dramatic. The Mackenzie Valley is by and large a homogenous habitat for mammal species. It is homogenous in the sense that yes, there is a mosaic or a pattern of vegetative development and changes in topography. But by and large there are recurring, this pattern recurs as one travels the length of the

1 Mackenzie Valley. There is greater diversity to
2 the south. There is more of a mixed wood forest community
3 which Dr. Bliss had photographs of. As one progresses
4 northwards down the valley, the coniferous forests
5 predominate, however by and large the Mackenzie Valley
6 is fairly homogeneous. This homogeneity however,
7 is broken up by riparian areas. Riparian areas are
8 simply water course habitat. Where a diversity is
9 introduced in riparian areas one gets the develop-
10 ment of shrub vegetation, a diversity of tree species
11 which in turn is reflected in the diversity and the
12 abundance of mammals which exist there.

13 As a consequence, because the
14 various water courses and stream courses which enter
15 the Mackenzie Valley are quite important because they
16 provide that diversity.

17 In contrast, the northern
18 Yukon, quite diverse. One can see from this map
19 mountains, rolling plateaus, the great expanse of
20 the Old Crow Flats, as well as quite a wide belt
21 of tundra. There is forest tundra occupying the
22 Peel and the Porcupine Plateaus in this area here.
23 Alpine tundra on the mountain merging into wet and
24 dry tundra right along the north slope.

25 So there are few topographic
26 as well as habitat differences between the Mackenzie
27 Valley and the northern Yukon.

28 One of the things that is of
29 interest is that most of the mammal species which
30 are found within this geographic area occur in other

R.D. Jakinchuk
In Chief

1 parts of Canada. The beaver for example which
2 extends right up to the Mackenzie Delta is just as
3 common in the waters of the Ottawa River within
4 sight of the Parliament Buildings, an example of
5 a very widespread species. Only polar bear and
6 the muskox and the arctic fox are those species
7 which can be really termed quite unique to the
8 northern area. Even caribou range down south of
9 60, some of the mainland herds of Canada.

10 Now, where you find the
11 various species depends on where their habitat
12 requirements are met. As a consequence
13 they tend to be clumped in their distribution,
14 these are the larger mammals that I am referring
15 to, such as beaver or such as caribou or such as
16 Dall sheep. They tend to be clumped according
17 to available habitat. The exceptions are the
18 microtine rodents which occupy a very, very large
19 area and, because their habitat requirements are
20 met over large areas, and another exception would
21 be some of the wide ranging carnivores, wolves and
22 wolverine which are not abundant in any given place,
23 but cover a very wide range of country.

24 I am not going to discuss
25 marine mammals to any degree except to say that there
26 are perhaps three important species that occur in
27 the Beaufort Sea, off the Mackenzie Delta. The
28 Beluga Whale or the White Whale, Ring Seals and
29 the Bowhead Whale which is not great in numbers
30 and may be an endangered species.

R.D. Jakinchuk
In Chief

1 THE COMMISSIONER: Was it
2 the Bowhead Whale that they used to come to hunt at the
3 turn of the century?

4 A That is correct, and
5 that was the subject of a very intensive whaling
6 effort throughout the north. That is the
7 reason for the base at Herschel Island or the
8 original occupation of Herschel Island.

9 In the discussion to follow,
10 I do have some slides which will illustrate some
11 of the points, but I have selected a number of
12 species that I will refer to because they reflect
13 either different characteristics or they occupy
14 differing habitats and I would like to comment
15 briefly on some examples of furbearing mammals in
16 the north, some of the large carnivore, larger
17 carnivores as well as caribou.

18 The Barren Ground Grizzly
19 Bear. Widely distributed in Northern Yukon and
20 in the lower Mackenzie Valley. Found throughout
21 the mountainous areas and the foothills and along
22 granges and particular that go into the tundra.
23 There appears to be quite a substantial population
24 of Barren Ground Grizzly on Richard's Island in the
25 Mackenzie Delta. There are Grizzlies that have
26 been observed, particularly in the lower part
27 of the valley and their densites have been located.
28 They are a species which is omnivorous. They feed on
29 both plant and animal material. They are capable of
30 killing caribou or moose, but they sometimes do, they

1 sometimes eat carrion, they will dig after ground
2 squirrels, they will even make themselves a salad
3 out of horsetail equisetum. They are an extremely
4 impressive species and extremely important carnivore --
5 well I just said that they are an omnivore, but they
6 are classified in the -- as a carnivore -- sort of
7 officially.

8 One of the most interesting
9 elements of the Grizzly and one of the most important
10 habitats of the Grizzly -- as I say, they range
11 over quite a wide variety of habitat, is their denning
12 area, and for both Grizzly and arctic fox here is
13 where the environment permafrost creates a constraint.
14 The Grizzly has adapted itself to that environment
15 when food is scarce by going into a period of dormancy
16 which may last for six months -- say, October to
17 May.

18 There are only certain limited
19 areas, however, where they can either find a natural
20 rock cave, or conditions are suitable for them to
21 excavate a den and have a mantel of snow cover that
22 den to such a degree that their energy and heat
23 is preserved. So denning areas for Grizzlies appear
24 to be at a premium in the North. They appear to
25 be used repeatedly for generations. For example,
26 there are some den sites just north of Old Crow that the
27 Old Crow people say have been used since the memory
28 of the grandfather's grandfather and you are looking
29 at perhaps a period of 150 years.

30 This is what represents in

R.D. Jakinchuk

1 my discussions to follow, a key or critical habitat
2 element, something which is important to the
3 population of mammals, important to their survival
4 and perpetuation. So den sites are very important
5 for Grizzly.

6 It appears that there are
7 much more Grizzly bears, encouragingly enough, in
8 the northern Yukon and Mackenzie Valley than was
9 previously thought prior to much of the intensive
10 survey work that has been done over the past five
11 years. There have been some sophisticated studies
12 dealing with Grizzlies recently which include
13 immobilizing bears and following them with radio collars
14 which is contributing/a considerable amount to our
15 knowledge of bear biology.

16 However, from a survey
17 standpoint, a numbers standpoint, they appear to be much larger in number
18 than previously thought.

19 I may change the order here.
20 I will leave the porcupine caribou herd until last,
21 I think -- no -- I had better carry on.

22 Porcupine Caribou herd. The
23 subject of intensive study by many agencies. By the
24 gas industry, by state and federal officials in Alaska.
25 By the Federal Government in Canada. Very, very little
26 was known about this herd up until five years ago.
27 Since then it has probably become one of the most
28 intensively studied caribou herds around. It is very
29 important, one of the major herds in the north. The
30 major herd west of the Mackenzie River, it numbers in

R.D. Jakinchuk
In Chief

1 the order of 110 to 115 thousand animals. It displays
2 an interesting annual cycle, probably the most
3 dramatic annual cycle of any ungulate in Canada,
4 because it migrates over long distances. It occupies
5 a very wide range of habitats. It has a pattern
6 of movements and distribution which exhibit
7 consistency over the years, even though there are
8 some variabilities.

R.D. Jakinchuk
In Chief

1 Consistency in terms of
2 the direction of movement as well as the timing of
3 movement, the timing of certain events in the life
4 cycle of the caribou, and timing, of course, is a
5 very important thing for survival in the north. Things
6 have to be done at the right time or dire consequences
7 might result. To give an example, I would just like
8 to cite an example of the timing. Where the synchrony
9 is greatest is in calving; 1972, the onset of
10 calving 27th of May, the peak, 5th to the 7th of June;
11 1973, the onset, 28th of May; the peak, 5th to the 7th
12 of June; 1974, the onset, the 27th of May; we didn't
13 have a peak but it finished in mid-June as it has in
14 the previous years. Probably one of the most predicable
15 elements of caribou biology is this calving.

16 Caribou occupy a very wide-
17 spread winter range. They engage in a spring migration
18 from that winter range that takes them to the north
19 slope, foothills and coastal plain calving area.
20 They calve. Following the calving there are -- there
21 is the development of post-calving aggregations, very
22 tight ^{Antelope} concentration which occur and have occurred
23 annually. They engage in clockwise summer movements
24 following the post-calving aggregation which takes
25 them from those portions of the aggregations in Alaska
26 back to Canada. I will illustrate this in a moment.

27 They engage then in this
28 summer movement, clockwise movement throughout their range
29 in the month of July; in the month of August they
30 disperse, another very dramatic event. They are

R.D. Jakinchuk
In Chief

1 thinly distributed throughout their range and they put
2 on their fat for their most rapid weight-gain during
3 that period. Then there is a coalescing again of
4 these dispersed herds and they engage in a fall migra-
5 tion. During this period they breed, the bulls and
6 the cows, and the fall migration takes them down to
7 their winter ranges and then the cycle is repeated annually.

8 I would like to show you some
9 of these movements in distribution of the porcupine
10 herd. Each of these reflects four or five years of
11 data and it will give you an indication of what the
12 similarities and some of the variabilities that have
13 been documented. Here are the wintering areas. Now it
14 looks very squigly but I'd like to point out there
15 is four years of information on this, that has been
16 generalised to show the general trend. The brown is
17 the year 1970 and '71, red is 71-72; the blue is
18 '72-73 and so on. You will notice that it's the
19 winter, it's an international caribou herd. The
20 winter range can be either in the drainages of the
21 Chandalar and the Yukon River in Alaska, with Arctic
22 Village in the centre, the Porcupine Peel Plateau
23 generally in the headwaters of the Peel and Porcupine
24 drainages. There is a component that is wintered on
25 the Richardson Mountain and has utilized the alpine
26 tundra, and there have been periodic anomalies occur
27 in this wintering. You will notice that the biggest
28 change in the sequence of events is in 1973-74 where
29 caribou wintered where they hadn't been documented
30 wintering before, and this was a period in which there

R.D. Jakinchuk
In Chief

1 was virtually very, very low snowfall and virtually
2 no snow to speak of on the north slope, and north of
3 the normal wintering range, so they were able to main-
4 tain themselves over the winter in those areas. The
5 one thing that this map does not show is the relative
6 wintering density. The density, the numbers of
7 animals wintering in these areas is higher; for example
8 this whole area represents 2,000 animals. This may
9 represent in this year, I forget the exact figure,
10 50,000 or something of that nature.

11 THE COMMISSIONER: Dr.

12 Jakinchuk, excuse me, just so that I can orient
13 myself, is Old Crow somewhere in the --

14 A This is Old Crow here,
15 and the Porcupine River, the Old Crow Flats here,
16 Aklavik and the Richardson Mountain. O.K., so there
17 is several years of information on the wintering areas.

18 This is called the early
19 winter movement, that's basically that period follow-
20 ing the fall migration. Once again, you see four
21 colors there and you'll see that there is a parallelism
22 in the general trend of these movements. The fall
23 migration of the porcupine herd after the summer disper-
24 sal, a coalescing, a coming together of the widely
25 dispersed animals into groups that gradually increase
26 in size, and the migration that exists down to the
27 winter range may take them right to the Ogilvie Mount-
28 ains. In some cases the fall migration, following the
29 fall migration period there have been movements into
30 Alaska.

R.D. Jakinchuk
In Chief

1 This is a very interesting
2 one on the post-calving movement. I should have calving
3 area before that. The post-calving movement that
4 exhibits a clockwise tendency and have exhibited this
5 -- I'm sorry, these things go together but they just
6 become a little more complicated. There are four years
7 of data. I'm just going to use the one, all four
8 years exhibit the same tendency, a clockwise following
9 the calving period movement of caribou throughout the
10 northern Yukon and into Alaska.

11 I have a slide later on showing
12 a caribou fence and I'll comment more on that de-
13 vice used to capture caribou during those movements in the
14 past.

15 For three years surveys have
16 been carried out -- well for four years, surveys have
17 been carried out, as I say, by numerous agencies. This
18 represents a delineation of the calving ground. Those
19 areas where calving has taken place, and you'll notice
20 that there has been a variability documented. However,
21 the highest density of calving, generally, I would say,
22 occurs from the Firth River on the Yukon to the Jago
23 River in Alaska, despite the variability that has
24 occurred in the total extent of the calving area over
25 the year. This variability is a response to some
26 of the conditions that caribou, I feel, a response to
27 some of the conditions that they meet on their migra-
28 tion -- barriers which exist as a result of flooding
29 rivers, snow conditions and so on. This causes them
30 to make adjustments in where they drop their calves.

This is where, immediately in

July, soon after the calving period, which is another period of dispersal, these large post-calving aggregations ^{have} take place, right along the coast, just prior to the onset then of this summer movement.

Now the spring migration, of course, the number of animals that go along any given route are -- reflect the number of animals that wintered in an area. This looks like spaghetti, I admit that, but once again it's four years of information that has been overlaid. There is two main -- in the Yukon, two major corridors of migration during the spring. What has been termed the Richardson route, up along the Richardson Mountain, and the Old Crow route, a migration from the central part of the Territory that goes up past Old Crow, adjacent to it and to the Old Crow Flats, culminating in either calving in parts of the Yukon or calving in Alaska. Migrations also, this reflects migrations in various years from those caribou who wintered in Alaska.

The period, the onset of migration may vary from the, oh, 1st of April till the middle of May, the onset. There are two essentially, in several years, two waves of migration that have been documented on the Richardson route. In other words there tends to be an earlier migration that starts here, and a later migration that also goes up, and whereas the timing of the spring migration on the Old Crow route has been much more consistent and we are postulating that one of the reasons for this apparent two waves of

R.D. Jakinchuk
In Chief

1 migration on the Richardson route is the snow condi-
2 tions in the valley of the Peel River and the Peel
3 River itself. Very, very deep snow that until such
4 time as it subsides could effectively curtail the
5 onset of the migration.

6 O.K., I will be saying more
7 on the porcupine herd when I get to my slides.

8 I should mention two other
9 sub-species or species, whichever you want to term them,
10 of caribou -- woodland caribou, which are widely dis-
11 tributed on both sides of the Mackenzie Valley, with
12 their most northern distribution being in an area -
13 I think that's Travaillant Lake there. There appears
14 to be a group of caribou here that there's some confusion
15 about, as to whether they are woodland caribou or whether
16 they are members of the reindeer herd, the established
17 reindeer herd, or whether they are hybrids of some
18 kind. It is our belief that they probably represent
19 the northernmost extension of woodland caribou. There
20 may be 2,000 animals in that area. However, woodland
21 caribou are found on both sides of the Mackenzie
22 Valley, they are unlike the barren ground caribou, they
23 are found in small groups, perhaps up to 20 or 30
24 animals. They do not engage in long migration, they
25 engage in seasonal movements within a fairly restricted
26 range. They're scattered, extremely hard actually to
27 find. The focal points, however, may be the Travaillant
28 Lake area. This area west of the McConnell Range
29 appears to be an important woodland caribou area.
30 Another one is the Horn Plateau over here, for woodland

R.D. Jakinchuk

In Chief

1 They occupy to some degree
2 the fens in the summer period, their main habitats
3 are the Black Spruce lichen forests and the alpine
4 tundra which is found on some of the higher plateaus
5 and ranges.

6 Just passing reference to
7 the reindeer herd which utilizes the Tuktoyaktuk
8 Peninsula, it is unlikely that they would ever
9 interbreed with barren ground caribou, their breeding
10 characteristics are a bit different. They
11 breed earlier in the fall and they drop their calves
12 a month earlier in the spring time. It has been specu-
13 lated that some of the herds that are found in the
14 more interior areas east of the Mackenzie may have
15 approached the Mackenzie River historically, but
16 I think in our discussion of these mammals, those
17 caribou which are important in the northern Yukon and
18 Mackenzie Valley, we should limit pretty well our
19 discussion to the Porcupine herd and the Woodland
20 caribou.

21 Moose as a species are
22 widely distributed also throughout Canada, not just
23 throughout the Mackenzie and northern Yukon.
24 Quite a remarkable species in as much that they
25 have exploited opportunities that take them right
26 to the -- right on to the tundra. One's first
27 impression when flying over much of the vast area
28 of the Mackenzie Valley is that it must be loaded with
29 moose, it is all -- looks like moose pasture and a
30 good moose range. Well, unfortunately the conditions

R.D. Jakinchuk
In Chief

1 of snow make 99% of that range inhabitable for moose
2 for the winter period, so that moose engage in seasonal
3 movements, they exploit the habitats available to
4 them, both in the Yukon which includes the
5 tundra as well as the Mackenzie Valley during
6 that summer period but are constrained back to those
7 winter ranges which have snow that is not crusted and
8 not too deep and has a supply of shrub upon which they
9 can feed.

10 Once again, one finds with
11 some that the riparian areas, the small drainages
12 entering the Mackenzie River are important for moose
13 during winter. The islands of the Mackenzie River, from
14 about Wrigley to Fort Good Hope, sustain a lot of
15 moose winter utilization. These islands are important.
16 However the moose have to clear off of them before
17 the flooding takes place in the spring and they do
18 and they head inland and they disperse and occupy,
19 in the summertime primarily the aquatic habitats --
20 the shallow marshy lakes where they feed on aquatic
21 vegetation to a large degree during the summer periods.

22 Concentrations, as I say, do
23 occur in the wintertime, moose are characterized, both
24 in the northern Yukon and the Mackenzie Valley, by these
25 seasonal shifts in their population dynamics -- or
26 sorry, seasonal shifts.

27 Dall sheep. The white sheep
28 of the north. There are no Dall sheep found on
29 the east side of the Mackenzie Valley at all, although
30 some of these mountain ranges, the McConnel range

R.D. Jakinchuk
In Chief

1 In particular looks like it is a suitable habitat for
2 this species, they have never been recorded there.
3 They are widespread in their distribution in the
4 southern Yukon, in the Mackenzie Mountains. As one
5 proceeds north, however, and here we are in the
6 Yukon, there are scattered populations that occur in
7 some of these ranges. But as one proceeds, in our
8 main focus area focus, the northern Yukon,
9 there are only two populations which are discreet and
10 important.

11 One, a population of 450
12 to 500 sheep is found in the Mount Goodenough
13 area of the Richardson Mountains and occupies seasonal
14 ranges of approximately where my pointer is.

15 Another one is found adjacent
16 and west of the Firth River, some distance inland from
17 the coast. It is only about 60 animals and actually
18 the most northernmost Dall sheep population in
19 Canada.

20 The Mount Goodenough popula-
21 tion is hunted by the people of Aklavik and as I say,
22 the most significant in terms of numbers in the northern
23 Yukon.

24 Sheep also engage in seasonal
25 movement throughout their range. They require speci-
26 fic habitat elements such as escape terrain where they
27 can escape from predators or disturbance. It is
28 important to them. They tend to exhibit a high degree
29 of social behaviour and traditional behaviour which
30 has allowed them to survive once again in a northern --

R.D. Jakinchuk
In Chief

1 in a rugged northern area.

2 Small mammals. Arctic fox.

3 A few words on Arctic fox. For this species, they
4 are generally associated with the tundra. The highest
5 density of fox dens which have been found in studies
6 over the last five years are on Herschel Island and
7 generally in the delta areas between the Malcom
8 and the Firth River.

9 The distribution of fox denning
10 habitat diminishes as one goes eastward towards the
11 Mackenzie Delta. Most of the concentration of dens
12 are found within generally this area. There are fox
13 ranges during the winter of course through out including
14 the ice pack of the Beaufort Sea. There are also
15 denning areas on Richard's Island.

16 Now, these dens are important
17 to the raising of young, the whelping of young.
18 They are also at a premium. Suitable sites for denning
19 are very limited in permafrost terrain. Either the
20 ground is frozen and the fox cannot dig in it or it
21 is inundated with water. I will show you some
22 examples of that in the slides.

23 Arctic Fox exhibit, as I say,
24 the fluctuations in numbers from time to time, apparently
25 in response to the fluctuations that occur in Lemming
26 population. They are quite an elastic species in as
27 much as they have -- in time when food is scarce
28 they raise few numbers of young -- approximately four
29 to five per litter. If there is a high lemming popula-
30 tion, the Arctic Fox is able to explode its own

population by recorded whelping of up to 20 pups.

They range widely in the winter time. They feed on carrion, off kills from polar bear. During the summer period they are -- the females in particular are in dens raising young.

Muskrat. Not a very dramatic species, but an important species in the trapping economy. They are a species which requires wetland complexes. Habitats primarily lakes, which have quite a high degree of aquatic vegetation upon which it can feed and lakes which are deep enough so that it can survive over the winter and is not frozen out and probably one of the main habitat limitations to muskrat are -- is the amount of ice or the amount of water available on lakes.

The muskrat area in northern Canada has got to be the Old Crow Flats. Great lacustrine plain that is a mosaic of thermokarst lakes. Not all which meet their habitat requirements of muskrat, but a large number of which do.

Muskrat are widely distributed where wet land habitat is available. Muskrat are widely distributed on the Mackenzie Delta, for example. The Old Crow Flats is a key area for muskrat. They are found to some degree in the area such as the Ramparts - Ontonagon river systems here. And throughout the valley where, as you can see on this map there are wetland complexes exist. Their populations fluctuate from time to time, freeze out during the winter is a real important

1 environmental constraint for the muskrat.

2 Beaver. Once again, widely
3 distributed, occupying habitat which may be either
4 slow meandering streams or lakes where there is a
5 food supply available. In the food for beaver,
6 the quality of the food decreases as one goes
7 northward down the Mackenzie Valley from southern
8 areas. Therefore they have adjusted
9 their food habits. They will feed on birch for
10 ~~example in northern areas where aspen is a preferred~~
11 food in the south.

12 Beaver have adjusted to a wide
13 number of problems. Beaver introduce thermokarst
14 for example. Probably one of the reasons why
15 they are not a really successful species on the Old
16 Crow Flats is that everytime that they build a dam
17 in pond water, thermokarst is established on the
18 edges of the dam and the dam washes out on them.
19 They have been known as nature's engineers. Well, they
20 also perform a very important function ecologically
21 in the north because of their damming activities and
22 capabilities. They slow down this flash period of
23 runoff in the spring, help maintain water and distri-
24 bute it over a longer period of time. In the creation
25 of ponds behind dams they open up as a result of
26 thermokarst activity, open up vegetation and provide
27 edges of vegetation which is valuable for other species
28 of mammals. They tend to create an edge and a diver-
29 sity by their activities.

1 Key areas for beaver. This
2 area of the Ramparts-Ontaratue River here is considered
3 by many to be the best beaver area in the Northwest
4 Territories. It has got a very high population.
5 They are on both the lakes as well as the meandering
6 drainages. Very important beaver area. There are
7 beaver on the Old Crow Flats and in the Mackenzie
8 Delta, but the densities of beaver are not high.
9 I suspect on the Mackenzie Delta, the dramatic effects o
10 of the break up and the flooding in the spring is
11 not favourable to the species.

12 Another key area for
13 beaver is in the drainage of the Kakisa River, large
14 number of lakes and small drainages which enter the
15 Kakisa River. Populations are very high there.
16 However, one could virtually find beaver lodges
17 and beaver habitat on any of the slower meandering
18 streams and some of the lakes throughout the Mackenzie
19 Valley. They are widespread. Low-gradient streams
20 in particular. They are important for trapping around
21 Fort McPherson.

22 I want to -- I do not want
23 to bore you.

24 THE COMMISSIONER: In
25 your own way. You carry on in your own way.

26 A I have to discuss the
27 marten. It is an animal that is not very often seen.
28 But it is an important upland fur bearer and the reason
29 I will devote a few words to the marten is that it is
30 one of the species that appears in the trapping catch.

1 Its distribution is synonymous with the distribution
2 of mature forests -- spruce and in mixed wood forests,
3 particularly in southern areas where there is
4 aspen or polar and spruce -- mixed wood. Widely
5 distributed, dependent, its habitat is essentially
6 is the mature forest. Its main prey species are the
7 microtine rodents, although it is quite versatile in
8 feeding on prey. Found on both sides of the Mackenzie
9 Valley and in the Yukon where there are stands of
10 mature forest. Definitely not an animal of the
11 alpine tundra or the arctic -- or the low arctic
12 tundra.

13
14 Populations -- to give you
15 an idea of what a dense marten population is, the
16 densest population that has been found is in this area
17 of the Cameron Hills, the Redknife Hills down in
18 the south. Two per square mile has been documented
19 there by various -- you know -- trapping techniques and
20 so on, whereas by and large, the populations for which
21 their density information is around .4 marten per
22 square mile in and throughout most of their habitat
23 in the Mackenzie Valley. Once again, this might be
24 and I say, "might" be a correlation with increasing
25 productivity of prey species as one goes southward.
26
27
28
29
30

R.D. Jakinchuk
In Chief

1 It's important to trapping,
2 riparian habitat once again in the Mackenzie Valley
3 are used to a high degree by martin. They are a carni-
4 vore, they rely upon catching live prey, killing it
5 for their food.

6 Having given a thumbnail
7 sketch of some of the mammal species that occur within
8 the area, I would now like to briefly discuss rare and
9 endangered species.

10 I have tried to come to terms
11 with what is a rare and endangered speci
12 ,at legislation, by looking at lists that people have
13 prepared, and contacting governments, and it's an
14 area of a great deal of vagueness at the present time.
15 It's virtually impossible to establish what a rare or
16 endangered species is, because it depends on who you
17 talk to. The only consistent government authority
18 could find for rare and endangered are polar bears.
19 Now I should make mention of that specifically. The
20 polar bear which ranges throughout the Beaufort Sea
21 has been known to den on Herschel Island, and has been
22 known to generally, to some degree concentrate there
23 because of the leads in the ice around Herschel.
24 But they also are found along the shores of the islands
25 of the Mackenzie and up to Bailey Island; in the Northern
26 Yukon, however, the Herschel is probably the main
27 area of polar bear activity.

28 Polar bear is considered by
29 the Canadian Wildlife Service under the rare and
30 endangered classification. Other classifications which

R.D. Jakinchuk
In Chief

1 exist on the Statutes have placed barren ground
2 caribou and muskox , mule deer and elk in the North-
3 west Territories on the rare and endangered list, or
4 as endangered species, I should add. Well, it
5 doesn't make a great deal of sense to me for some
6 of these species, and it's kind of an anomaly, but
7 I should mention it. It's an area, I think, in which
8 governmental Wildlife Agencies are going to have to
9 get their heads together and sort out. The categoriza-
10 tion of what is rare, what is endangered, what is
11 rare and endangered, is important to those species
12 that might be vulnerable to depletion. However, they
13 are only going to be accorded that protection if there
14 is sufficient information known about their status and
15 subsequent legislation.

16 I consider, for example, a
17 vulnerable species to be the barren ground grizzly
18 bear. It is also considered to be vulnerable by most
19 agencies, but it has no official status. So in summary
20 on rare and endangered, I would say that the situation
21 is presently in a mish-mash, as far as I can deter-
22 mine, and it's extremely difficult to deal with.

23 THE COMMISSIONER: Excuse me.

24 Dr. Jakinchuk, did you say that the barren ground
25 caribou is classified by some agency or agencies as
26 rare and endangered?

27 A There is a Statute,
28 an Order-In-Council, I believe in the Northwest Territories
29 dated 1960 which classifies the barren ground caribou
30 as an endangered species, and I don't know what the

R.D. Jakinchuk
In Chief

1 reason was for doing that, but it doesn't ^{to me} make a great
2 deal of sense because caribou are very widely distri-
3 buted in the north and there are a number of large
4 herds of them. However, they were in 1960 accorded
5 protection by Statute. Now that still exists, as far
6 as I know, but I think it's not an up-to-date classi-
7 fication.

8 I would like to talk briefly
9 about the sensitivity and the resilience of mammal
10 species in the north. Once again I'm forced into
11 some generalizations but I have a couple of examples.

12 There are many mechanisms
13 which operate in mammals which indicate an adaptive
14 capability, and a resilience in terms of their ability
15 to survive and perpetuate themselves. But this is a
16 generalization. The degree of resilience and the
17 degree of sensitivity can vary according to species,
18 and here I've got two examples, one of which is the
19 Arctic fox, which can be a very productive resilient
20 creature. Arctic fox tend to be tame, they're not too
21 disturbed by human activity, as a matter of fact they're
22 drawn in many areas of their range to human activity.
23 When times are good in terms of prey, they can increase
24 drastically in number. They seem to have a pretty good
25 reproductive and productive resilience. They breed
26 at an early age, for example.

27 Take the barren ground
28 grizzly as an example of a somewhat more sensitive
29 and less resilient species. Throughout its North
30 American range, gradually it has been declining in

R.D. Jakinchuk
In Chief

1 numbers, as human society expands. But there is one
2 thing, there appear to be a lot of them in the Northern
3 Yukon, in the lower part of Mackenzie Valley and
4 North-east Alaska. They are not as resilient, however,
5 as a mouse which can bring off several litters a year,
6 or as an Arctic fox, or even as a caribou in my view
7 because of the fact that they reach breeding age at
8 such a late time. Recent information has indicated that
9 the barren ground grizzly does not breed until it's
10 five years of age, and does not, in that part of the
11 north that we're talking about, is not successful in
12 rearing and raising cubs until the age of eight years.
13 Now this is information that hasn't been written up
14 yet, so it seems to me that that species, the grizzly,
15 is not a resilient species. If something happens to
16 the grizzly, it takes a long time before they can
17 reproduce themselves in number again, and this is the
18 way that we have to look at all of the mammal groups
19 in terms of their sensitivity. How resilient are they?
20 How well can they bounce back from an environmental
21 condition, from a disturbance condition? Some
22 species appear to me to be more sensitive to human
23 disturbance than others. Dall sheep appear to be
24 more sensitive, for example, than barren ground caribou.
25

26 I think the key thing is that
27 northern mammals have to exhibit all of their resilience
28 because of some of the very severe environmental constraints
29 they have to deal with. Mammals as a resource.
30 When we think about traditional activities of hunting

R.D. Jakinchuk
In Chief

1 and trapping and fishing, mammals have played, for a
2 long time, an important role as a resource that is
3 utilized by humans. The porcupine caribou herd, for
4 example, has been harvested for many hundreds of
5 years by the people of Old Crow and other communities.
6 At the present time, porcupine herd is subject to
7 harvest by the people from Fort McPherson, from Aklavik,
8 from Old Crow, are probably the main villages that
9 utilize the porcupine herd. There are others such as
10 Arctic Village Taktovik in Alaska.

11 Moose are also ^avery important
12 food source, subsistent species, utilized by virtually
13 all of the communities up and down the Mackenzie, as
14 are woodland caribou, for Mackenzie River communities.
15 The only place the Dall sheep are very regularly pursued
16 in terms of human utilization are by people of
17 Aklavik that harvest in the order of 50 to 60 Dall
18 sheep a year from the Mount Goodenough population.

19 Trapping. Trapping has al-
20 ways has been important in the north or in the last
21 100 years, an important means of obtaining income
22 from mammals. Probably the hey-day of the real
23 full-time professional trapper was in the 1940's, and
24 trapping activities have been declining over the last
25 decade or so. I think the decline is probably related
26 to other types of employment opportunities and acti-
27 vity, to the extent that there are probably more part-
28 time trappers now up and down the Mackenzie in places
29 such as Old Crow than there are full-time trappers.
30 That's not, to say that part-time trapping isn't

R.D. Jakinchuk
In Chief

1 important, because it does provide, you know it does
2 provide a link with activities that have high social
3 value. But there are not a large number of full-
4 time trappers up and down the Mackenzie, the number
5 has been declining.

6 Major communities for trapping
7 include Aklavik, Fort Rigley, and Fort Simpson, in
8 terms of the number of pelts produced, although
9 others -- for example, Old Crow, Arctic/^{Red}River, Fort
10 Norman, Providence, are also focal points of trapping
11 activity.

12 The specie which are most
13 important vary from community to community. For
14 example, Trappers at Old Crow concentrate on ~~caribou~~
15 Trappers from Fort Good Hope have access to these
16 large beaver populations I was talking about on the
17 Ontaratue and Ramparts River so there is a large catch
18 of beaver in that area. The species which are most
19 important in the trapping economy are beaver, muskrat,
20 lynx, martin, and mink. They are important fur species
21 in terms of the numbers, and the amounts trapped.

22 Other human utilization of
23 mammals include, in the north, includes sports hunting,
24 primarily in the Southern Yukon animals are hunted.
25 Dall sheep are particularly prized, and the porcupine
26 caribou herd is now exposed to sports hunting by
27 the advent of the Dempster Highway through portions
28 of their winter range, and this is a case where a
29 monitoring of the harvest, the utilization of its
30 population is important inasmuch as that population

R.D. Jakinchuk
In Chief

1 has been exposed to a new force, in this case the Demp-
2 ster Highway, so that while sports hunting by southern-
3 ers is not generally important in the Mackenzie Valley
4 per se, or in the Northern Yukon and the more
5 southern areas of the Yukon, it is ^{an} important industry.
6 it generates a lot of guiding revenue and so on.

7 Aesthetically, mammals are
8 utilized aesthetically, very hard to define how one
9 would feel about a large group of caribou or how one
10 might respond to a little mouse; but the aesthetic
11 importance has increased, I believe, over the years and
12 will continue to increase, so this is another way in
13 which mammals can be utilized by humans.

14 The levels of utilization and
15 the potential for utilization vary. Just very generally
16 I would say that in the immediate areas of communities
17 there is probably some likelihood that moose are over-
18 utilized. Where they're accessible, moose are pretty
19 good eating and it may well be that moose are over-
20 utilized in the immediate vicinity of some communities.
21 I think that the Dall sheep population on Mount
22 Goodenough is probably at the maximum utilization level
23 that it can sustain by the present harvest that takes
24 place. Incidentally, sports hunting by southern hunters
25 is not allowed on that population. The porcupine
26 caribou herd, I think, has a greater potential for
27 utilization by hunting than is presently -- than the
28 take which exists at the present time. However, it's
29 something that has to be carefully monitored in terms
30 of the productivity of that population.

For example, Old Crow, I think, will take five to 700 caribou a year; 300 or 400 from Aklavik, a couple of hundred from McPherson and so on through the north; but then we have the new ingredient of the hunting on winter range along the Dempster Highway that has to be looked at.

R.D. Jakinchuk
In Chief

1 In terms of trapping potential,
2 it would be my view that there is a much larger poten-
3 tial for the harvest of mammals through trapping than
4 is presently exploited. I don't -- I can't think of
5 any situation where I would consider that there has
6 been ^{an} excessive trapping effort that has harmed or
7 depleted the population. I think there is a very great
8 hinterland potential for trapping up and down the Mac-
9 kenzie, in other words utilization levels are nowhere
10 near the danger level.

11 With that I want to get into
12 my slides, so if you'll turn the projector on. O.K.,
13 we're going to show a sequence of the porcupine
14 caribou herd starting with the staging for the spring
15 migration, and here is about 1,200 caribou on a mountain-
16 top, south of the Porcupine River on the Keele Range.
17 Interestingly enough, they often occupy these very
18 very high elevations where you don't expect -- you
19 would expect to find sheep but not caribou. But they
20 do feed on the lichen at these higher elevations, and
21 there is evidence that as a result of temperature
22 inversions, the temperature is often much warmer at
23 these higher elevations than on the valley floor. The
24 valley floor to the left may not be utilized because
25 of snow conditions or lower temperature.

26 When the migration commences,
27 it's a very, very dramatic thing. It's directed
28 movement towards the calving ground in the spring.
29 Much of the Boreal Forest, the forest tundra is just
30 a maze of trails and caribou activity as the animals

R.D. Jakinchuk
In Chief

1 stage up and prepare for their migration.

2 As they head northward, these
3 trails are aligned in a linear way with the direction
4 of their movement, and you know, very readily are picked
5 up from the air. Here is how they go at times, in
6 single file through deep snow to save energy. This
7 particular column, the columns can be several miles
8 long, they're primarily in the initial migration is
9 primarily all pregnant cows, the cows on their way to
10 calf. The bulls follow by some period of time. So
11 what you're looking at here is cows and yearling
12 animals in this long dramatic line heading north to-
13 wards the calving grounds.

14 I mention ed something about
15 the adaptations. This gives you a very good picture of
16 how rounded the caribou hooves are, they are rounded,
17 they have dew claws, they are able to support the
18 weight of the animal over very varying types of
19 terrain, including the very soft musket, bog and tundra
20 that they traverse. There was a slide missed back
21 there. Something happened to it. O.K.

22 In the course of the migration
23 caribou encounter and overcome many, many obstacles,
24 including swollen rivers after breakup. This is a small
25 group of cows that are swimming across the Porcupine
26 River. In the course of their travel they climb high
27 mountains, they cross rivers, and there is mortality
28 that takes place amongst them because of the dangers
29 that they encounter along the way. Till they reach
30 the calving ground, those areas primarily of the tussock meadows,

R.D. Jakinchuk
In Chief

1 the cotton grass, the rolling benchland, the coastal
2 plain area of the north slope of the Yukon and Alaska,
3 at which time the animals tend to spread out, they have
4 their calves. There is a cow and a calf on the edge
5 of the Jago River in Alaska.

6 Here is a view once again from
7 Alaska with the Jago River in the foreground, which is
8 just about the westernmost point of the concentrated
9 calving, looking south towards the Brooks Range,
10 showing a typical terrain which is utilized by calving,
11 on and adjacent to the coastal plains, with rolling
12 foothills particularly important.

13 As I described earlier,
14 following that period the very dense aggregations that
15 occur, the animals come together in dense aggregations,
16 post-calving. The bulls come into the calving herd.
17 The calves are mobile with their mothers, and this is
18 just prior to the onset of their summer movement. Once
19 again the dense aggregations occur in July, and the
20 summer movement pattern begins this clockwise pattern
21 which I showed you on the overhead projector earlier.
22 You can see the bulls, this is a mixed herd, cows,
23 calves and bulls. They roam throughout the foothills
24 and tundra, these large herds, sometimes compact, some-
25 times strung out. There is a crossing, what is
26 approximately 10,000 caribou, barren ground caribou
27 on the Kith River during the course of summer movement.
28 There they're crossing the braided Consett River in
29 Alaska, also part of the Porcupine caribou herd.

30 You can see from these

R.D. Jakinchuk
In Chief

1 | photographs, the great diversity of terrain that in the
2 | course of the year a caribou encounters, and here is
3 | the penetration of the group into the Brooks Range,
4 | into the British Mountains. I think this is the British
5 | Mountain area, where during August the large aggregation
6 | tend to disperse and the animals become sprinkled
7 | throughout the mountains, throughout the foothills and
8 | throughout the coastal plains. This is a caribou
9 | fence north of Old Crow, right here, made out of wood
10 | from the very few trees that exist in this transition
11 | from the forest to the tundra, and it's got a wing on
12 | it here, and I believe that's -- you know, I believe
13 | that might be over 100 years old. You can see a very
14 | long spur of the fence vaguely coming down here. These
15 | might stretch for miles, sometimes up to five miles.
16 | In the course of survey, the intensity of surveys
17 | carried out on the porcupine caribou herds, some 30
18 | of these aboriginal fences have been located in
19 | Alaska and Canada, and when one plots their location
20 | on a map, and one plots the summer movements of
21 | caribou, these fences are located where they will
22 | coincide with these major movements. This is a piece
23 | of indirect evidence, for example, that there is this
24 | consistency in movements over quite a long period of
25 | time. All of these fences haven't been aged. The
26 | earliest -- the latest that one has been used is
27 | probably 60 years ago, near Arctic Village in Alaska,
28 | but they may range back for over 300 years in age.
29 | Then of course, the forerunners of the present Old
30 | Crow people and those members of the Vantikuchin in

R.D. Jakinchuk
In Chief

Arctic Village were the constructors of these fences. This is the way they secured caribou during the period of the summer movements. Caribou are gradually funnelled into the trap, at which time they were either bludgeoned or speared or shot, not with guns but with arrows. So that's an interesting feature of the historical use of caribou, and as I say, a large number of these artifacts have been discovered throughout the summer range of the Porcupine herd, and as a matter of fact this has been written up as a separate entity.

When I talk about microtine rodents, it's a good idea to give you a look at one. This is a yellow-cheeked vole in the vicinity of Chick Lake, and on the east side of the Mackenzie River. That's what a vole looks like, it's about eight inches long. They're quite large. When we speak of a group of mice and microtines, these are the ones that are at the base of the food chain. There is a red ^{back} vole, once again similar location. They're the type of things you don't see unless you go out to trap them, but they're there and they're important. There's a weasel, this photograph is a weasel in its summer colors, an ermine is another word for it. In the summer they're both brown and white, not the pure white. They are one of the species that are widespread, they are found right from Southern Canada right up to the tundra area. Here is a martin. Unfortunately I could not secure a photograph of a martin in its natural habitat. This one is coming out from under a tent at a study area, and actually that's the head of a martin, it's not the whole martin.

R.D. Jakinchuk
In Chief

1 But also called the pine martin, they are probably the
2 most widespread and important upland fur-bearer in the
3 Mackenzie Valley, and they are harvested, they are
4 trapped, they are pursued quite regularly by trappers
5 and form an important part of the catch, probably not
6 as important as the times when ladies used to wear them
7 as wraps around their necks. That what happened to a
8 lot of martin in the '30's and '40's.

9 Arctic ground squirrel,
10 Larry Bliss has already shown you a picture of one of
11 these. I haven't discussed it specifically, but they
12 are very, pursued quite vigorously by grizzly bear.
13 They go into a very deep state of hibernation during
14 the winter, and are distributed where there are well-
15 drained ice-free permafrost, or ice-free soils. This
16 is a stray muskox and it came over from a transplanted
17 group in Alaska into the Firth River country, and he
18 wandered away from this group of about 30 or 40
19 animals that had been transplanted and worked his way
20 into the Northern Yukon.

21 This is a wolverine. ONce
22 again, a species that is not commonly seen, that is very
23 difficult to define a habitat for, they are widely
24 distributed and never found in high numbers.

25 Dall sheep on their late --
26 this is late winter or early spring, whichever you want
27 to term it, and two Dall sheep rams. There are Dall
28 sheep on summer range bedded down. There's something
29 wrong there. When I discussed habitat components earlier
30 I made reference to escape terrain. You see, here is

R.D. Jakinchuk
In Chief

1 a good example of escape terrain. It's extremely
2 precipitous, where / ^{that} animal can find a number of
3 opportunities and is very well adapted to escaping from
4 predators, so that's a habitat component that has
5 nothing to do with vegetation, it has to do with the
6 topography.

7 I mentioned specifically the
8 Mount Goodenough sheep population. It is very difficult
9 to see, this is just a small group of seven rams there.
10 What is interesting are the feeding craters up on this
11 plateau. This is taken in late winter, actually taken
12 in March. You see evidence of where the sheep were
13 pawing through the snow for forage, and their inter-
14 connected trail. Subsequent studies of this population
15 has shown that even during the wintertime they are
16 found at these high elevations, at these exposed
17 elevations, and the reasons become apparent. They
18 are blown free of snow by the wind, where snow tends
19 to drift in the valley, and one very interesting fact
20 is one measurement was made, a temperature measurement
21 was made, I think in February of '73, where there was
22 a 40-degree difference in temperature between the
23 top of the ridge, as a result of a temperature inversion
24 and 2,000 feet below in the valley. So here is another
25 reason why the sheep are found right on the top rather
26 than down into the timbered area.

27 Moose. I indicated the wide range
28 of habitat they occupy, here is a bull moose on a
29 lake in the Old Crow Flats. Once again, typically
30 utilizing an aquatic habitat during the summer period

R.D. Jakinchuk
In Chief

1 where there is aquatic vegetation. There are virtually
2 no moose on the flats themselves in the wintertime
3 because primarily of snow factors, but they are found
4 around the edge so there is seasonal movement to and
5 from the Old Crow Flats.

6 Here is two bull moose near
7 the Firth River, right out on the tundra, and for those
8 people who might be from Ontario who associate moose
9 with Ontario forest conditions, it's a remarkable
10 place to see a spotted track on the moose.

11 Here is an example that I
12 think very vividly portrays the association between
13 moose and their habitat during the wintertime. Now
14 I had to go to an Alaskan example for this photograph.
15 This is part of a concentration of 22 moose, adjacent
16 to the Amituryouak River, and here you see the willow
17 protruding above the snow, and here is where the moose
18 are, and there is where they can't survive.

R.D. Jakinchuk
In Chief

1092

1 There is an Arctic Fox in
2 summer peltage. The one in the spring just before it
3 has changed, but not a very good photograph of a fox.

4 I mentioned the denning areas
5 being very important. Well, they are -- only fairly
6 finegrained soils, well drained soils are suitable
7 for denning and that is where they occur on braided
8 rivers, in dune areas, on pingos and in some cases
9 frost heaves and so on. Not too gravelly, silty
10 sandy soils are utilized for denning, where they are
11 sufficiently frost free that burrows can be established.
12 And here is, in the middle of a braided river delta,
13 is an Arctic Fox den and it stands out very, very much.
14 The reason it does is the prey of the fox, the remains
15 of the animals it brings in, its own excrement provides
16 nutrient to that area and the -- such areas are so
17 poor in nutrients they respond dramatically just from
the organic material associated with a den and
you can see it stands out like a sore thumb.

When I mentioned the resili-
ance of the Arctic Fox, this is a vixen that has
utilized a pile of lumber near a cavitic river on the
north slope of Alaska. It is a den site. Now, that
says two things to me. It says one, that den sites are
pretty hard to come by and secondly that the fox
is capable of making use of its opportunity. That
particular pile of lumber produced the wealth of six
arctic fox in the summer of '72.

Here is a close up view
of a den showing the relative luxuriance of the

In Chief

1 vegetation associated with it. This is of course
2 how you find them. The luxuriant vegetation as opposed
3 to the surrounding areas. ONce again wherever you
4 add nutriants to arctic soils they are capable of
5 responding in the summer.

6 These are two red fox.

7 I use the term red fox pups, but the term cross fox
8 comes from a colour phase of the red fox and here you
9 see one black one, one the typical red -- this is
10 a cross fox. They come within the same litter,
11 they are just colour phases and when I alluded
12 earlier to interspecific competition, a very clear
13 case of that is the expansion of red fox into white
14 fox territory.

15 For example, there are
16 red fox occupying arctic fox dens on Herschel Island
17 and they appear, you know, they are competing for
18 the same living space with the white fox and they
19 appear as if they might be successful in pushing them
20 out. Here is one of the factors that works to regulate
21 and govern populations. Competition between species.

22 This is a wolf den on a well
23 drained hillside, a close up view of one of the
24 entrances. There is a barren ground grizzly bear --
25 a formidable looking creature. A lot of them during
26 the summer time tend to be very light in colour. IN
27 the spring they occupy river drainages, those that
28 are vegetated by willow. They utilize carrion from
29 wolf kills. When they emerge from dens they --
30 then they disperse into moutain valleys and they

1 utilize rivers again to a high degree in the fall.
2 Very capable of looking after themselves, but no match
3 for a hunter's bullet.

4 There is a Grizzly on the
5 Old Crow Flats -- once again an entirely different
6 type of habitat, shortly after emergence with a
7 caribou kill, feeding on a caribou kill. Whether
8 he killed it himself or it was originally
9 killed by wolves, I do not know.

10 Here is a bear den right
11 at the base of this rock bluff. You can see the
12 tracks that the bear has made shortly after emerging
13 from the den. This is a cave den and in the studies
14 that have been carried out, interestingly enough most
15 of the dens for the Grizzly have been found at about the
16 3500 foot elevation, just about where the shrubs
17 cease to grow.

18 Here is a view from inside
19 a bear den looking out.

20 MR. GENEST: What happened
21 to the photographer?

22 A This is something
23 that you approach very carefully, this type of sit-
24 uation. Because of the fact that the Grizzlies,
25 after they emerge often hang around the area and
26 then come back for a period of several days
27 before they start to disperse. You can just see the
28 fact that some plant material has been pulled in to
29 line this den and some of the cave dens, the rock
30 cave dens, particularly in Alaska, where we found

1 most of them, have been well lined with vegetative
2 matter and appear to be utilized over a long period
3 of time. So that is the bear's view when he
emerges in the spring time.

The mixed wood forest is
basically throughout North America the habitat of
the Black Bear and this is just in the Norman Wells
area and there is a sow and two cubs in the
typical habitat situation. The Mackenzie River is
in the background.

These -- I am getting
into a series of habitat shots now, showing the
different habitat types and terrains that are
utilized by mammals. For example, the caribou are on
polygonal terrain here. This is taken during the
time of their summer movement.

Here is a view from
the Old Crow Flats looking towards King Edward
Mountain, part of the Old Crow Range and there are
several bear dens in those mountains.

A view of the Mackenzie River.
Dr. Bliss had a very good description of the eco-
system of the Mackenzie Delta. Once again it is a
mozaic. It is diverse. It is a good area for muskrats
but it does not support to a very high population
level of other mammals. But one must remember
27 that the Delta is an area that is really subject to
28 a lot of flux and change. Icing, break up, flooding
29 and so on, which intends to inhibit such species as
30 moose for example which could make very good use

1 of the abundant willows and alder in the delta.

2 This is looking to the west
3 across the delta to the Richardson Mountains and
4 when I referred to the Mount Goodenough Call sheep
5 population, that -- this is it looking towards
6 the general area in which they occur, along the
7 west side of the delta.

8 This is a barrier beach on
9 the Beaufort Sea. I threw this in to show
10 you the type of area that Arctic Fox might forage in
11 for either birds' eggs or carrion. They do utilize
12 these barrier beaches during the summer period.

13 This is a very large area
14 of tussocks, cotton grass tussocks. During the period
15 of the August dispersal. Now it may be difficult
16 to see, but you can see caribou sprinkled here and
17 there and when I mentioned this dispersal and showed
18 these other maps, this is characteristic of the
19 August period, they spread out. They feed and put
20 on weight remarkably on the lush vegetation of the
21 tundra and the uplands and this is taken in the
22 northern Yukon during August and is either coastal-
23 plain or the next thing to it.

24 Here are the -- this is
25 looking south -- Richardson Mountains, basically
26 the foothills of the Richardson Mountains, looking
27 south and once again these areas of well drained
28 tundra are utilized during the summer and during the --
29 particularly the August dispersal -- that
typifies the type of place one might find caribou during

this period.

Here is once again a duplication of what Dr. Bliss had, but it is the cotton grass tussock area. This is pretty well typical of where caribou calve -- this type of terrain. The cows -- when they arrive at the calving grounds make very high use of the unopened buds of the cotton grass. It must have a very high nutrient value, because they graze extensively on those buds and the distribution of cotton grass tussocks may be one of the reasons why caribou calve where they do.

Here is a view of the Old Crow Flats showing some of the wind oriented lakes. Many of the lake shores are flat, as a result of wind action and this great extensive mosaic of lakes and spruce forest in between and so on -- area that the caribou move through during their summer movements, the moose utilize during the summer-time, a great area for muskrat and not so great for beaver.

Typical winter range of caribou, the open black spruce, tundra, you will notice how the snow is all disturbed -- that is where caribou have gone through and fed and cratered. You can follow these disturbances in the snow and as a consequence delineate winter ranges, but that is a typical view of the type of habitat they occupy during the winter period. One of the reasons they do it is because the snow is

1 generally soft and they can paw through it or hoof
2 through it in an area such as this, as opposed to
3 wide open areas where the snow becomes crusted and
4 here is how they -- this is a feeding crater and
5 they utilize their hooves to remove the snow and
6 feed on the underlying, whether it be sedge or
7 lichen -- underlying vegetation.

8 I mentioned the importante
9 or riparian areas in providing diversity and habi-
10 tats for quite a wide array of mammal species.
11 This is Lord Creek which drains into the Porcupine
12 River, taken in the fall to show you the
13 diversity -- the deciduous component and the
14 well-treed meanders of this river, of this riverine
15 area that is a pretty important habitat, not only
16 for the smaller mammals and the furbearing mammals,
17 but for moose.

18
19
20
21

R.D. Jakinchuk
In Chief

1 You can see the contrast
2 provided the surrounding terrain. Snow depth.
3 This once again is in the Mackenzie Valley, and a pretty
4 poor winter habitat actually. A moose has gone through
5 about four feet of snow here, and has to plough its
6 way. You can see that that's a pretty substantial snow
7 depth, getting pretty well to the critical level. There
8 is nothing for a moose in this kind of habitat in the
9 winter. You don't see a zig-zag pattern of tracks, he's
10 moving through.

11 Here in the vicinity of Holmes
12 Creek adjacent to the river where the moose tend to
13 come down for the winter there's a great deal more
14 activity, once again associated with the riparian
15 area. A view of the valley itself, as I say quite
16 homogeneous, gently rolling benchland, more precipitous
17 topography on either side. There is a fen, sometimes
18 these areas are used by woodland caribou in the summer-
19 time. Here is an example of the diversity that -- of
20 habitat that's provided by a lake. Instead of a homo-
21 geneous expanse of forest, the fact that the forest
22 canopy has been opened by the water has resulted in a
23 large number of plant communities in proximity. It's
24 diversity, and as a consequence it supports a larger
25 variety and number of mammals than the more homogeneous.
26 You can see here birch, there are alder and willow
27 on the periphery, sedges on the edge, gradually blending
28 into the black spruce forest. So once again areas of
29 diversity provide best or very important habitat.

30 Here is another view of this

R.D. Jakinchuk
In Chief

1 mosaic, this complex of vegetation which forms the
2 habitat of the Mackenzie Valley, a component of birch
3 in with the spruce. There's a close view right
4 adjacent to the banks of the Mackenzie River, showing
5 a lot of -- I guess it must be birch -- deciduous
6 growth anyway, that can be utilized by moose as browse.

7 Going to human utilization, this
8 photograph was taken several years^{ago} by a friend of mine,
9 it's a moose that was taken near the Ramparts area.
10 Good moose steaks are good for you.

11 This is a muskrat hunting
12 basically camp on the Old Crow Flats. Some caribou were
13 taken during the spring migration, and they are being
14 dried on that framework for future use.

15 Here is one shot of a beaver
16 taken on the Old Crow Flats in the vicinity of that
17 same camp. The chap on the right is Jerome Thomas, and
18 that's Mary Cassie of the Village of Old Crow.

19 Here is a nice looking series
20 of muskrat pelts that resulted from the late winter and
21 spring trapping period. They have been skinned, they
22 are turned inside out, put on stretchers and dried and
23 fleshed, put together in bunches like this and their
24 next destination is the fur auction.

25 With that I will close my
26 presentation. Thank you.

27 THE COMMISSIONER: Thank you,
28 Dr. Jakinchuk. You were most lucid and interesting
29 and helpful.

30 (WITNESS ASIDE)

1 THE COMMISSIONER: Mr. Scott?

2 MR. SCOTT: Mr. Commissioner,
3 could we adjourn now? For what period of time would
4 you like to adjourn? I think this afternoon we will
5 only be hearing one overview witness.

6 THE COMMISSIONER: 2:15.

7 MR. SCOTT: Until 2:15, sir.

(PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

MR. SCOTT: Mr. Commissioner, a number of the expert witnesses we have been calling in the overview have expressed their concern to me about the requirement that they take an oath, and they have logically and sensibly advanced the proposition that because so much of their evidence is in the nature of opinion evidence based on their studies, or their examinations, that the oath seems inappropriate insofar as it requires them to tell the truth about which they can only speculate. It seems to me that there is a certain logical -- there's a certain logic in that observation, but we must ask them to bend to the requirements of the quasi judicial proceedings, and I have explained to our expert witnesses what therefore is required of them is not that in response to the oath they should tell the absolute truth in God's own mind, but rather they should give their true opinion to the Commission and to that extent they are satisfied, I think.

I would like next to call
Professor John Livingston.

JOHN A. LIVINGSTON, sworn:

THE SECRETARY: Will you state your full name, please?

A John Livingston.

DIRECT EXAMINATION BY MR. SCOTT:

Q Professor Livingston, I understand that you are a graduate of the University

J.A. Livingston
In Chief

1 of Toronto.

2 A That's correct.

3 Q And that you are at
4 present a professor in environmental studies at York
5 University in Toronto.

6 A Yes.

7 Q And that you have been
8 interested in environmental affairs for some substan-
9 tial period of time.

10 A Yes.

11 Q Could you tell the
12 Commission something of your work in environmental
13 matters, and the particular expertise that you have
14 developed in those years?

15 A I've been working in a
16 practical sense with birds for some 30 years, and I've
17 worked a lot in Africa and elsewhere in the tropics,
18 most particularly in the Galapagos Islands. For the
19 past six or seven years has been chiefly restricted to
20 the Canadian Arctic.

21 Q And when you say it's
22 been restricted to the Canadian Arctic, do I under-
23 stand that for the past six or seven years you have
24 at least over several months of the years spent your
25 time actually in the Arctic or sub-Arctic?

26 A I have spent most of my
27 summers in the field in the Arctic for the last half-
28 dozen years.

29 Q Yes, I see. Now I also
30 understand, doctor, that you have been retained in the

J.A. Livingston
In Chief

1 past to do some work for Arctic Gas, or the company
2 formed by Arctic Gas to do environmental work.

3 A Yes, up until 1974, just
4 about a year ago, I was the principal member, principal
5 investigator for ornithology for the bird work that was
6 done for Canadian Arctic Gas.

7 Q I see, and could you
8 tell us briefly just for the record what your work
9 for them involved?

10 A My personal work con-
11 sisted initially of course of research design in the
12 identification of problems, and then the mounting of
13 the research effort and data analysis and drawing
14 conclusions and writing up the report. I spent a
15 great deal of time in the field, though.

16 Q Yes, and I take it, doctor,
17 it won't be necessary unless there is a requirement
18 later for some cross-examination, but I take it that
19 you have participated in the traditional organizations
20 of bird men and written the required number of articles.

21 A Yes, this is true.

22 Q Well, as a fellow Toron-
23 tonian, welcome again to the Arctic, and would you
24 carry on?

25 A Thank you very much.

26 Mr. Commissioner, I have to
27 echo the comments of a couple of my colleagues about
28 generalization to the extent that it's impossible to
29 package, as it were, northern birds, and deliver them
30 up in some kind of generalization with some degree of

J.A. Livingston
In Chief

1 confidence. In the area indicated on our map here
2 we have literally scores upon scores of species of
3 birds, a wide variety of families. So it follows that
4 an extrapolation from one species or a group of species
5 to another is a bit difficult, what I would say would
6 be quite dicey, really.

7 Another difficulty that we
8 always face in ornithology is that the birds are some-
9 what less known to the public at large than the mammals
10 and fishes. Everybody, I am sure, knows what a caribou
11 looks like. Everybody thinks he or she knows what a
12 Arctic char looks like; but the world is full of
13 people who haven't the faintest idea of what a
14 Hudsonian dogwood is, or what a buff-breasted sandpiper
15 is. That's simply something with which we have to live
16 and we can't do anything about that.

17 But the big problem with
18 generalization on these northern creatures, even the
19 most closely related ones, often have very profound,
20 very important differences in things like behaviour and
21 habitat requirements and life history and ecology
22 ganerally. For example, we have in the area four
23 different species of breeding geese, and each is
24 completely individual in the way that it operates its
25 life cycle -- its migration routes, its nesting habitat,
26 food habit, its moulting patterns, and all the rest
27 of it. Each is very different from all three of the
28 others, so usually it doesn't help us very much to
29 talk about geese in general, because often as not you
30 have to refer to individual species.

J.A. Livingston
In Chief

1 But even within one species
2 different age groups, for example, have different
3 requirements, different times of the year, and even
4 different populations ^{and} different parts on the map
5 may have different ways of doing things, during their
6 life cycle. I don't apologize for all this, it's
7 simply in the fundamental nature of things, when I
8 talk about things you haven't heard about simply because
9 I must.

10 I would also emphasize at this
11 point that no attempt will be made by me anyway to
12 categorize bird species in rank order of importance.
13 Some species are more numerous than others, but that's
14 not a measure necessarily of the ecologic importance.
15 Some are more conspicuous than others. Some more
16 striking, some more interesting, some more appealing
17 in the aesthetic sense than others are, but none of
18 these are a measure of a species ecologic importance,
19 and I say this now because students are forever asking
20 me to list the important species in some eco-system
21 or other, and I steadfastly refuse to do that because
22 it's impossible to arrive at that kind of a judgment
23 in the ecologic sense.

24 Now as we go along I'll try
25 to make reference to the level of existing knowledge
26 where it's appropriate or it seems useful to do that.
27 I want to review briefly what northern birds are all
28 about, some of their characteristics they have in
29 common. As everybody else has and will point out,
30 when you go from south to north, say from equatorial

J.A. Livingston
In Chief

1 to Arctic regions, you get a progressive reduction in
2 the number of species there, including birds. In the
3 north, too, distributions tend to get patchy. We have
4 optimum habitat conditions, such as you've seen in some
5 of the slides. You're going to have what I would call
6 oases of birds, and these are surrounded by generally
7 very wide stretches of virtually empty landscape, at
8 least superficially empty. But in these oases you get
9 usually a small number of species tending to predominate
10 in terms of numbers, and also of course we have colonies,
11 especially out at sea. Colonies are traditional sites.
12 We have highly social species that jam in together and
13 nest together in enormous concentrations. Things like
14 snow geese and some of the auks and other sea birds
15 like that.

16 But species that are not
17 colonial -- and most bird species are not colonial --
18 these tend to be more or less loosely scattered through
19 the available habitat, the peculiar habitat of their
20 species, and so their density in a given place at a
21 given time depends entirely on the availability of that
22 habitat, and the richness or thinness of that habitat
23 in terms of supportive capacity. Then some birds are
24 more territorial than others, and that means that some
25 birds demand and defend bigger chunks of territory
26 against their own kind than others do, and some are
27 more vulnerable to attacks by predators than others
28 are, and some need -- there may be a limited number of
29 sites of the right kind to protect these birds within
30 a given area. All these things cut down on the

J.A. Livingston
In Chief

1 density of breeding birds, so you can see the attempt
2 at generalization breaks down rather rapidly. Just
3 to give you a perspective on the thing, in Canada we
4 have something slightly in excess of 520 bird species.
5 Of these, only about 75, plus or minus a couple, about
6 75 regularly occur north of tree-line in the Arctic
7 proper. If you go down southward through the tree-line
8 region, through the forest tundra into the Boreal Forest,
9 the numbers increase, of course, quite rapidly until
10 when you get down to the southern parts of the country
11 you have a maximum diversity in terms of bird species.

12 Now in the Arctic proper again
13 north of the trees, about three-quarters of the species
14 we have are circum-polar. By that I mean that they
15 occur also in Eurasia, as well as Canada and Alaska.
16 Among these are all of the loons that we have there,
17 a couple of the greaves, some of the geese, many of the
18 ducks, most hawks, grouse, most shorebirds, gulls,
19 yagers, hawks and a couple of owls. Of the remaining
20 quarter of the Arctic species, there are either very
21 similar sort of replacements, as we call them, or
22 opposite numbers of very similar things that occur
23 again in the Old World. Most of them are.

24 Now if you go down south
25 through the delta, down the valley and into the Boreal
26 Forest eventually and finally the open prairie way below
27 in the prairies, you begin to lose these Old World
28 affinities and find it virtually lost altogether.
29 The southernmost parts of the region, if you get
30 down into Alberta, the birds species are almost entirely

J.A. Livingston
In Chief

1 American. Also up in the Arctic proper north of the
2 trees about 45% of the breeding species belong to one
3 single order, which is a taxon, an assemblage of families
4 of shorebirds -- gulls, terns, auks and things like that,
5 45% of them. Next in importance of the number of
6 species, 23% of the birds of the north are waterfowl --
7 swan, geese, ducks, and there are the loons, four of
8 them as I have mentioned, miscellaneous others, to the
9 point that three-quarters of the birds of the true
10 Arctic are water-oriented, are water birds of one kind
11 and another.

12 Now as I say, they're not
13 distributed evenly over the landscape, especially up
14 in the north. As I said, it's patchy, it's quilt-like
15 really. Much of the high Arctic archipelago is vir-
16 tually desert, so far as birds go. They concentrate
17 where there is a dependable supply of food, one way or
18 the other, and that means vegetation to produce the
19 things they need for the summer, and others live in
20 these colonies that I've described. So except for
21 sea birds, vegetation is the key.

22 Of course it follows that
23 since most of the north, the far north, is virtually
24 empty of birds, those places where birds do occur end
25 up being of critical importance. But generally speaking
26 the banks of streams and the edges of lakes and
27 ponds and the edges of the polygons you saw in the
28 pictures, and the wet tundra, tend to produce more
29 birds, both in terms of numbers of species and numbers
30 of individuals, than most other habitat type do, and

J.A. Livingston
In Chief

1 that's not to say that there aren't birds specifically
2 tied to dry tundra and other things because they are,
3 but generally speaking, in terms of absolute numbers,
4 the wetter^{it} is, the more attraction there is in terms
5 of birds.

1 Now, in all ecosystems
2 the greatest variety of animal species tends to
3 occur at the edges of habitats. This has been
4 alluded to earlier today. Places where two habitat
5 types abut or join or merge or mingle or whatever
6 you want to say because there you have the best of
7 two worlds, so this is quite important. An ecologist
8 calls this phenomena the "edge" effect and every
9 experienced bird watcher knows that the action is
10 at the interfacing, he goes to the interfacing
11 between two habitats.

12 Now, one of the best examples
13 of that is the forest tundra ecotone itself which
14 is not really a treeline. As you know, it is a
15 zone of many couple of hundred miles thick where
16 spruce and tundra meet, mingle.

17 Yes --

18 THE CHAIRMAN: Excuse me,
19 what was that word you used? Eco --

20 A Ecotone. T.O.N.E.

21 I am sorry for the jargon, Sir. It is just one of
22 the words. It means the interface between two
23 systems.

24 Now, this treeline area
25 or spruce tundra area is kind of a zone of tension,
26 or I like to think about it that way, sort of pushing
27 and pulling. You have the tundra and the spruces
28 fighting, as it were, for the zone, retreating some
29 years, advancing other years. That tension seems
30 to produce positive results in terms of the variety

1 of species that live there.

2 Also, these ecotones,
3 these overlapping edges between habitat types
4 tend to have their own special species that are
5 tied directly to that kind of habitat and do not
6 occur in either of the larger areas on either
7 side. So you have got this tree line or forest
8 tundra zone being richer in species than either of
9 the ones on either / side of it and just as ponds and
10 lakes produce that kind of an edge effect around
11 their edges, all around the tundra, in the boreal
12 forest down south you will find the same effect all
13 around the edges of where it has been burnt at some
14 point or the margins of lakes and marshes and the
15 like of that.

16 Now, these places are usually
17 more productive in terms of species than the more
18 homogenous areas, forest that surrounds them.

19 But of all the edge effects
20 in the world known to ecologists, none is so productive
21 as the edge of the ocean. Most especially where you
22 have estuaries, deltas and things like that. I will
23 have more to say about that in a bit. For the
24 moment I just note the critical importance in terms
25 of bird support systems, of wet coastal tundra and the
26 aquatic systems along side them.

27 So with increasing latitude
28 you get decreasing numbers of species. That is the
29 first thing. Now that does not necessarily mean
30 that there has to be as an immediate result of that

1 a greater number of individuals of those fewer
2 species. I know that you hear this a lot, but I do
3 not think this is necessarily so. The abundance
4 of birds, you see, depends entirely on their support
5 system and the productivity of the habitat, the
6 individual site in question. It is very important
7 to remember that most ecologic pronouncements are
8 site specific in situations specific. It is not
9 susceptible to extrapolation from one site to another
10 even though they may look very similar, and so
11 the Arctic, just because it has fewer species than
12 the boreal forest below, does not of necessity have
13 more individuals of those fewer species. ON the
14 contrary, I think that is debatable. Because the
15 birds happen to concentrate in places where habitat
16 conditions are right, you can get the impression of
17 great numbers of birds and then you immediately
18 extrapolate to the gigantic area of the Arctic as
19 a whole and you come up with an overwhelming number
20 of birds and of course, that is -- simply is not
21 so.

22 It is like the little man
23 from Mars that seems to be coming down to a place
24 called Aransas Pass on the gulf coast of Texas some
25 time between November and April and he gets out of
26 his machine and he sees 40 or 50 whooping cranes
27 standing around and he says, "My lord! This planet
28 must be covered with whooping cranes and of course
29 that is all there are". That is an exaggerated
30 example of the kind of thing that we tend to do if

1 we do not understand the very precise and situation
2 specific distributions of these creatures.

3 So having in mind the limited
4 avail-
/ability of optimum habitat much less, you know,
5 even minimum habitat, but having in mind the enormous
6 areas of unsuitable habitat conditons, you might
7 conclude that population levels are not in fact all
8 that impressive and I do not believe they are by
9 comparison with areas farther south. A good example
10 of that, I guess would be the Whistling Swans in the
11 Mackenzie Delta. There are several thousands of
12 them. Six or seven thousand any way, I guess, in
13 the Delta and flying over, you get the impression
14 of an awful lot of swans. But even there they
15 are concentrated to some extent in optimum habitat
16 and the important thing is that there are few if
17 any whistling Swans anywhere else in the region
18 under inquiry here. Only very few places are suitable
19 for them and most of them happen to be in the Mackenzie
20 Delta.

21 so I think that it should be
22 said that despite what we read in the popular press
23 sometimes, ecologists are just as leery of generaliz-
24 zations as any other scientists are and ecology does
25 not in fact cast up as many generalizations as a quick
26 glance at the popular literature might suggest.
27 But there are a few basic tenets and one of those
28 is that in an ecosystem in general the stability of
29 the system appears to depend upon the multiplicity
30 of its component parts. The more variety, the more

1 diversity a system has, the more moving parts it
2 has, the more stable it is, the more resistant it
3 is to perturbation.

4 The more components an
5 ecosystem has, the more resilient it is, the faster
6 it can recover from damage of one kind or another--
7 natural damage I mean.

8 Now, this certainly appears to
9 hold true in the north temperate zone where most
10 of us live. It certainly appears to hold true in
11 the great hardwood region of the eastern part of the
12 continent. It does, the hardwood region is
13 diverse and it is extremely resilient and
14 recovers extraordinarily rapidly -- fire, insect
15 infestations, or flooding or whatever, and this is
16 a point where I remember to remind students that
17 coincidentally enough virtually all ecological
18 theory originated guess where? In the north tem-
19 perate zone because that is where the ecologists
20 live. But that rule does not in fact hold true
21 in two of the most diverse -- the two most diverse
22 ecosystems on earth which are coral reefs and
23 tropical rain forests and I am not going to go on
24 about them.

25 The point is that coral
26 reefs and tropical forests are quite the most
27 extraordinary diverse systems that there are any-
28 where and those are extraordinarily unstable in the
29 sense of resilience to disturbance. Disturbed, they
30 both collapse right in front of your eyes. They are

J.A. Livingston
In Chief

1 both extremely slow to get repaired and to recover,
2 and so the conventional wisdom about diversity and
3 stability does not hold in the tropics.

4 And neither I am beginning
5 to suspect does it hold in the Arctic. At least not
6 in the sense that the Arctic is fragile as they keep
7 saying simply because it does not have as many
8 species as tropical zones do. The north is patently
9 unpredictable, let's say, but I think that that
10 unpredictability is related more closely to fluctuating
11 populations than it is to the absolute numbers
12 of species present. I think that this is going to
13 be fairly important as we develop ecologic theory in
14 the north in the future. And I say the north is
15 patently unstable and unpredictable I take
16 into account these violent fluctuations that
17 you get that are well known in the populations of
18 so many animals species ^{we} will come back to that. It
19 has already been mentioned earlier. I do not think
20 that instability is necessarily the result of the
21 small number of species, I think that the ecologic
22 sensitivity of the north is a function of the level
23 of population of species at a given point in
24 time.

25 At the moment one happens
26 to be looking at them or measuring them -- whether
27 mammals or birds, different species happen to be on
28 the upswing or the down turn or whatever on the
29 skids in their cycles at that particular time.
30 As I emphasize again, ecology is situation specific.

J.A. Livingston
In Chief

1 The system may be fairly stable, temporarily stable
2 one place at one time and decidedly unstable at the
3 same place or another place some other time.
4

5 So in general as you move north,
6 species diversity goes down. Populations probably
7 also go down because of habitat constraints and
8 stability in the system if there is such a thing
9 as stability, is probably exceedingly variable both
10 in space and in time, and again, I emphasize this
11 varies according to the individual species and its
12 current population situation, and I cannot
13 generalize beyond that.

14 Now, I want to say something
15 about some of the dominant species that are in the
16 north, leaving aside for the minute the part south
17 of 60. We have here two major life zones, so-called
18 biomes, the Arctic tundra and the northern boreal
19 forest and inbetween we have a third which deserves
20 full recognition and full rank, I think in this
21 sense, and that of course is the spruce tundra system.
22 The ecotone to which I referred earlier that has its
23 own species.

24 Very broadly speaking --
25 you know the boreal forest, the spruce woods of which
26 you heard this morning, that is small bird country.
27 That is a terrible generalization but it is filled
28 with small bird species. Little dicky birds as
29 the ornithologists call them.

30 Now, the overwhelming number
of birds in the northern woodlands are as you would

J.A Livingston
In Chief

1 expect are boreal, they are birds that live in trees:
2 woodpeckers, flycatchers, swallows, wrens, thrushes,
3 warblers, the whole lot of little birds.

4 In habitats throughout there are larger things:
5 loons and waterfowl and birds of prey and grouse,
6 but in terms both of numbers of species and numbers
7 of individuals, the northern woodlands, the boreal woods
8 is characterized by small insectivorous birds.

9
10 To begin, very broadly
11 speaking, the Arctic is large bird country and this
12 is a profound difference: loons, waterfowl, birds
13 of prey, ptarmigan, gulls, things like that and
14 parenthetically I should say that small birds tend
15 to get along better with mankind than large birds do.
16 It has been calculated that of the birds of the
17 north, that is to say, north of the trees, a good
18 60% of them, the bulk is at least as big as a pigeon.
19 Whereas down in Ontario only 30% of the birds are
20 that large and that large of bulk is an adaptation
21 to heat conservation, just the same as it is in
22 mammals. Larger mammals have greater heat retaining,
23 heat conserving bulk inside, in proportion to a
24 body surface than smaller mammals do so they keep
25 the heat in there longer and hold it better and this
26 is why Mr. Jakinchuk tells us that the boles and
27 the lemmings and the things like that are somewhat
28 larger up there than they are farther south and the
29 bird species bulk larger also. It helps to be bulkier
30 if you are going to live in that sort of climate.

Now, later I will come to

1 some -- I will give some indication of the breeding
2 birds to be expected in some of the different habitat
3 types of which reference has been made of already.
4 Birds, just like mammals, just like the caribou
5 wandering all over the map of the Yukon through the
6 seasons, birds may nest in one habitat and feed in
7 another one. For example, some of the big birds of
8 prey will nest maybe quite a few miles away from
9 where they will go for hunting away from their nesting
10 site and this is known also in loons that nest on the
11 tundra lakes, for example, will fly quite a long
12 way out to fish in the sea, along the edge of the
13 sea and fly back again continually all day long and
14 this, remember, being something that one has to
15 study in terms of cost benefit energy trade offs in
16 the course of the nesting season. The farther they
17 have to fly, the more problematic it becomes

18 Geese and ducks, all water
19 fowl molt, loose their feathers. I am sure that you
20 have all seen a crow or a hawk flying overhead with
21 holes in its wings, it is molting, losing and re-
22 placing its feathers. It does this symetrically
23 and he can stay airbourne because he only does one
24 or two at a time, but swans, geese and ducks, when they
25 molt lose and replace their feathers, they lose all
26 of their flight feathers at once and they are
27 helpless until they replace them and can fly
28 again, and this is an extremely demanding period in
29 terms of energy and I will come back to that.

30 But they may go a long

J.A. Livingston
In Chief

1 way -- in this particular context -- they go long
2 distances to favourite moulting grounds that may lie
3 quite some -- many, many miles, sometimes hundreds
4 of miles away, sometimes close to a thousand miles,
5 there are some species that far go from where they
6 nested.

7 Scoters which are diving
8 ducks that nest away down, say, in the Old Crow or
9 some place like that will go all the way out to the
10 shore of the Yukon to molt where they are free from
11 disturbance during that period of about three and a
12 half or four weeks, something like that.

13 Swans that do not happen
14 to be breeding yet will spend the whole summer
15 season in a complex of channels in the Mackenzie
16 Delta that they never nest in. So again you
17 have got to consider a variety of habitats for
18 each species.

J.A. Livingston
In Chief

1 But in the fall when they
2 gather up in great flocks before migrating south, most
3 of the birds tend to congregate obviously in places of
4 maximum local productivity, biological productivity, and
5 these areas that wouldn't have been able to support
6 them all earlier in the year because it had to get
7 delivered its productivity. These areas, of course,
8 are critical, because of the dense concentrations of
9 birds. The north slope, as Dr. Bliss has already men-
10 tioned, is an example of a fall gathering / ^{ground} like
11 that for snow geese that come from a long way away, but
12 no snow geese nest there. So we have to think in terms
13 of the total cycle of the birds in order to make sense
14 again, we're being quite specific.

15 So when we talk about habitants
16 we have to define them in a variety of ways, according
17 to the different uses to which they are put by different
18 kinds of birds at different times, and these seasonal
19 requirements
20 / are just as specific as the habitat require-
21 ments are for nesting. In other words, a successful
22 hatch of birds does not mean a successful return to
23 their wintering grounds, as lot of things happen
24 in between.

25 I mentioned migration. All
26 animals have to make some kind of arrangement for winter
27 in high altitudes. Terrestrial ones have various
28 strategies, they can hibernate like the ground squirrel
29 but no northern bird can do that. There are birds that
30 hibernate, but not in the north. They can tough it out
better
like a muskox, a few birds do that, but / still of course

J.A. Livingston
In Chief

1 they can move out.

2 Incidentally, migration is
3 related not to the absolute temperature, it's really
4 got nothing to do with it, I think, it's related to the
5 availability of food. A bird has plenty enough
6 insulation in its feathers to hack any temperature
7 whatever, ~~because~~ they do it; but the food has to be
8 there in order to stoke the furnaces and so when they
9 migrate they're moving to a dependable food supply,
10 they're not moving away from the absolute cold.

11 Some of them feed as they
12 move, others do concentrated feeding in one spot, then
13 move quite a long way, then they'll do concentrated
14 feeding again. Some move on a wide front right clear
15 across virtually half a continent, and others tend to
16 be funnelled through quite narrow corridors, and these
17 are vaguely related to land forms and obviously water
18 systems, things like that, corridors like that; or
19 one of those inexplicable things that we call tradition.
20 We don't know what that means.

21 For obvious reasons the
22 energy demands in a birds' system are intensified
23 during migration, just as they are moulting or at
24 some other times. Some of them fly a long way. I
25 don't think I'll bore you with another recital about
26 the Arctic tern that goes all the way to the southern
27 oceans. We have breeding sandpipers from the north
28 slope of the Yukon that spend the winter in Patagonia,
29 a long way away. Most ^{of} /the waterfowl stay in North
30 America along the sea coast chiefly. Many of the song

J.A. Livingston
In Chief

1 birds end up in South America.

2 This, as I say, is terribly
3 demanding physiologically. The drain on the birds' fat
4 reserves is heavy. Those species that don't feed while
5 they're moving but have to stoke up and then use it
6 and then stoke up again, have a problem, and in the
7 north the most critical time is just before they go.
8 I'm talking about right along the Arctic shore. In
9 other words, there's only so much time after you finish
10 moulting to get airborne again. There's only so
11 much time to take on so much fuel, and disturbance at
12 that time could be a problem, and these consequences are
13 not subject to prediction yet.

14 We have to remember that all
15 these phenomenon are species specific. What applies
16 to white fronted geese or Canada geese does not apply
17 to snow geese. Now as they go along the birds are
18 drawing on their fat reserves all the time, and this
19 has gotten a lot of bird species into trouble, those
20 that have concentrated toxic chemical residues in their
21 fat, which is where these things lodge, they metabolize
22 them out of the fat and become poisoned. That's an
23 additional stress that a number of migrating birds are
24 subjected to. A lot of birds use weather fronts in
25 migration, and ride the edge of a front if it's going
26 in the right direction for that time of year, and that
27 helps a lot in getting a handle on what they're doing.

28 But again I emphasize the
29 short and the unpredictable northern season. This is the
30 problem, and the very fine timing. Reference has already

J.A. Livingston
In Chief

1 been made to timing that's required of birds as a
2 result that is required of all animals. They have
3 to get in the north, you see, not too early to find
4 themselves shut off from the food by the ice that
5 hasn't melted yet, but they can't stay -- they can't
6 afford to get there so late that they lose part of
7 that precious nesting season of six weeks or whatever
8 it turns out to be. They have to stay there as long
9 as they can, fuelling up before the cold weather comes,
10 then often it comes before they're prepared to go, and
11 we call that a poor year. So timing is probably the
12 most important element in the annual cycles of all
13 of North America.

14 Some species spend the winter
15 right out in the open sea. The ospreys do that, and
16 the jaegers that live with them through the year. Jay-
17 fowl drift out, but they only need to go as far as the
18 ptarmigan go, which isn't all that far. When lemmings
19 are scarce, the rough legged hawks and the snowy owls
20 go all the way down the continent right into the
21 Northern United States. These movements may become more
22 or less rhythmic, I imagine because I don't believe in
23 the four-year cycle any more than Ron Jakinchuk does;
24 you know, it varies from place to place, but these
25 movements may appear to become more or less rhythmic
26 according to the species and according to its prey.
27 The migration --

28 THE COMMISSIONER: You said
29 you didn't believe in the four-year cycle any more
30 than --

J.A. Livingston
In Chief

1 A Than Ron Jakinchuk, he
2 said that he was very hesitant to -- that's what I
3 meant to say.

4 Q I thought you meant a
5 species of bird there for a moment.

6 A For birds I don't believe
7 it. Anyway, this rhythmic movement back and forth, this
8 semi-cyclic or alleged to be cyclic movement, isn't
9 really migration because migration implies A to B and
10 back to A again on a regular yearly basis. We have
11 other kinds of seasonable movements on different sched-
12 ules.

13 Now I want to review a little
14 bit of the life cycles of some of the major bird
15 groups in the north, especially in the Arctic portion.
16 Most migratory, I have said they can't arrive until
17 spring breakup starts, and they can get at their food,
18 but when the season does come they have to get out
19 so quickly it's just a headlong rush almost to get
20 nesting immediately.

21 Now for all things there are
22 limitations to their proliferation obviously. We
23 don't fully understand how these things work but we
24 call them limiting factors for all organisms, there
25 are limits and there are things in the environment
26 which seem to be the enforcers of those limitations.
27 There are many factors involved in these vary from/
28 species, I want to mention just a few of them.

29 The best example, the easiest,
30 I suppose is the success of a predatory animal -- a

J.A. Livingston
In Chief

1 hawk or an owl or a wolf -- is governed largely by
2 the presence or absence of prey species. The lemming
3 dictates whether the owl is going to be there.

4 Nesting geese seem to be
5 constrained mostly by things like the brief ice freeze
6 period, occasionally they'll get shut out, there is
7 a very short season, a bad storm in June, something
8 like that, flooding and things of that kind, to some
9 extent perturbation. Waterfowl moulting as I said, when
10 they are helpless and can't fly have to have seclusion
11 from disturbance.

12 Down in the Boreal zone below
13 in the forest changes are more dramatic, fluctuations
14 in insect populations or in the fruiting success of
15 different kinds of trees can be an influence on bird
16 success.

17 Loons, we have four species,
18 all the four world species are here, they are common
19 right through the delta. Large lakes is often
20 sufficient food for them right there, but if they're
21 nesting on smaller ponds, tundra ponds or smaller
22 lakes they've got to fly to feed elsewhere, as I said;
23 some go right as far as the ocean.

24 We don't know much about them
25 in terms of their migration. They're very mysterious.
26 They turn up in the winter on the coast, but we're not
27 sure how they get there.

28 All four of them seem to be in
29 for trouble with toxic chemical residues which is having
30 an effect on their reproductive success. They are very

J.A. Livingston
In Chief

1 susceptible to disturbance. They can't fly readily,
2 they've got to taxi for 800 yards in order to get
3 airborne because they're so bulky in relation to their
4 wing surface. There are a lot of limiting things like
5 that and these are mostly anatomical difficulties
6 with loons.

7 Swans, we have two -- the
8 formerly
9 rare, / endangered now rare trumpeter swans we
10 found nesting in the Mackenzie Delta, but the whistling
11 swan is the main one that we have there, six or 7,000,
12 maybe. There are breeding lakes and ponds, they are
13 highly territorial, there will only be one pair on one
14 average sized lake as opposed to geese who will be in
15 there by the thousands. You get gangs of non-breeding
16 birds, not old enough to breed yet, they're scattered
17 through -- in flocks through the delta in the summer.

18 Moulting, there are some very
19 important traditional, and I use the word advisedly,
20 moulting areas in the delta that have been
21 pin-pointed and are available to you, I'm sure.

22 There are some critical places
23 for moulting that are available, I don't think I need
24 to recite them, they are all along from really Phillips
25 bay and the Babbage River right across to the central
26 part of Richards Island. We have four geese, but I
27 don't think I can possibly go through all of these.
28 There are very few Canada geese, not many. They are
29 scattered right through into the entire area on the
30 map here, but in terms of numbers they are not that
significant in our area. One of the important ones

J.A. Livingston
In Chief

1 is the Pacific Brant which is our smallest goose
2 and comes in the springtime away from around the
3 Pacific, goes right down the coast of Alaska along
4 the shore of the Beaufort Sea and ends up from
5 approximately the delta east. In spring they feed on
6 submerged ^{sedge} / underneath the salt water and later on
7 they come up to graze on the grass, but they're small
8 birds and so they're vulnerable to foxes, which most
9 other geese can fend off, but these things are not
10 much bigger than a duck and so they tend to nest out
11 on very, very small islands, very shallow islands
12 off on the outside of the delta there, where they are
13 of course, susceptible to flooding, but they'd rather
14 be there ^{than} safe from the foxes/inland where they'd get
15 them for sure.

16 So those low next areas are
17 susceptible to tidal flooding and that kind of thing,
18 and again there are traditional moulting grounds for
19 them.

20 The white fronted goose is
21 not that significant in the Arctic area, it's all
22 through, there are a lot of them, you don't see them
23 much but they're down under the willow shrubs and they're
24 hard to count, but there are big numbers that moult
25 around Kendall Island and Richards Island and eastward
26 of there.

27 The goose that gets all the
28 attention, of course, in the area is the snow goose,
29 and properly because they are so conspicuous and are
30 in great dense colonies. They use the Mackenzie Valley

J.A. Livingston
In Chief

1 flyway of course spring and fall. They will be nesting
2 by about the 1st of June, and that's where the element
3 of timing comes in. They're ready to lay the moment
4 they get there, they have to be in order to be able
5 to get out again in the fall.

6 In early September they
7 start ganging up and they're coming from a long way
8 east, some of these birds. Some are breeding birds
9 from the Mackenzie Delta, and some are beginning to
10 pour in from farther east, and they gather up in the
11 northwest corner of the Mackenzie Delta, approximately,
12 then they start fattening up there, feeding and they
13 all move in a mass over to the north slope of the
14 Yukon and Alaska for their major fuelling up before
15 they move south in migration, through the Mackenzie
16 Valley.

17 Ducks all through -- I don't
18 think I need to spend too much time on them, there
19 are many, many species of ducks and they're all
20 through the entire system we're talking about, from
21 the sea coast right up into the heavy woods. Again
22 the chief limiting factor with ducks, security, assum-
23 ing that the hatch gets off, security during the moult-
24 ing period.

25 Birds of prey, we have
26 numerous species scattered all through, according to
27 the availability of prey. The excipitors or bird
28 hawks are mostly down in the woods, they don't get
29 into the north, they're scattered, you rarely
30 see them. Soaring hawks including two species of

J.A. Livingston
In Chief

1 eagles, are throughout. We have one soaring hawk out
2 on the tundra, the rough-legged hawk, and it's tied
3 into the lemming cycles, if cycles they are.

4 The two eagles are both rare
5 and endangered, and subject to disturbance. The bald
6 eagle needs trees, it gets right up into the delta
7 but no farther. The golden eagle is out on the tundra,
8 and on cliff edges. Ospreys, the fish hawks, are
9 down somewhat farther south on forested lakes. The
10 killdeer, they have been all shot by pesticide residues
11 but they're not as intolerant to disturbance as eagles
12 are. We have two falcons of critical importance, of
13 course the very rare endangered Peregrine falcon and the
14 rare gyrfalcon, about which I'll say more when
15 we come to rare and endangered species. Again they are
16 limited by the availability of prey, and when ptarmigan
17 move out, the falcons move with them but they don't
18 migrate to any extent, they drift south. The Peregrine
19 falcon got into all its trouble because it's hooked
20 into the migrations of small sandpipers that go way
21 down south, and the Peregrine moves with them. There they
22 get the sandpipers, get into areas of maximum pesticidal
23 contamination. They sock it up and through the process
24 it's known as biological magnification they pass on the
25 dose to the animal higher up in the food chain and that's
26 how the Peregrine it appears, got into the perilous con-
27 dition it is in now.

28 Others, we have shorebirds
29 which are plovers and sandpipers and
30 things like that, all over the place, and I'll show

J.A. Livingston
In Chief

1 you a couple of slides of where these are, but they're
2 very specific, according to the species, in their
3 habitat, but all the way from cattail marshes and
4 sedge marshes to wet and dry tundra to beaches and
5 swamps, high mountain passes right up in the Brooks
6 Range, it just depends on the species.

7 We have owls, we have lesser
8 birds, we have as I say, far far too many to talk about
9 here.

1 I do want to come back
2 to a subject which Jakinchuk has raised about period-
3 icity, if indeed it is periodicity, fluctuations
4 in populations of animals. This is characteristic
5 more in the boreal zone so far as birds are concerned
6 than it is in the -- up in the Arctic proper. But
7 these fluctuations that you get in all species any-
8 way occasionally build up to really wild and violent
9 oscillations in populations, rarely predictable
10 among these boreal songbirds, and in the arctic of
11 course the changes in the lemmings affect three kinds
12 of jaegers and affect owls and hawks and things like
13 that. Grouse fluctuate as we have already heard, hares
14 fluctuate with concomitant fluctuations in lynx and
15 whatnot.

16 I suspect, however, these
17 have been described as the four and ten year cycles,
18 and I suspect that there are much longer cycles in
19 the north than we presently understand -- most
20 particularly in the Arctic.

21 Everybody has heard of the
22 lemming populations. The bird cycles are not so well
23 known and I would like to spend just a moment on the
24 way that these things occur in the boreal forest.

25 I do not think that we
26 should assume that fluctuations of the kind that we
27 experience both in the arctic and the boreal forest
28 are strictly northern phenomena, but they are more
29 visible in the north, I suppose, because of the
30 lesser number of species and thus the consequences

1 of these shooting up and overshooting and dropping back
2 and crashing again are more visible to the more
3 or less casual observer than they are farther south
4 where they tend to get damped out because you have
5 got so many species and so many habitats. Owls and
6 things like that can turn to other food farther
7 south than they can up in the north.
8

9 None of this is to suggest
10 that population cycles, if they are cycles, are at
11 all understood anywhere -- they are just more obvious
12 some places than others, ^{what} but is not understood at all
13 of course is the possibility of these longer cycles
14 that I mentioned and how these might match these long-
15 er population cycles with climatic cycles, maybe and
16 related natural perturbations.

17 You know, we would like
18 to know what would happen -- well, if you had the
19 coincidence say of a lemming crash ^{and} / one of those
20 periodic very short seasons that we get in the north
21 now and then. What would be the recovery period, if
22 two such events happened coincidentally? Well,
23 I do not know of course and nobody knows, but this is
24 the kind of thing that one needs to get into.

25 Cycles are interesting
26 enough, but to bird people even more interesting
27 are population eruptions, literally explosions of
28 populations that occur from time to time and they are
29 more interesting than cycles because they are not
30 predictable. We never know when they are going
to happen. You cannot say three years hence we are

1 going to have one.

2
3 As I say, most ordinary
4 migrations are scheduled in that they take
5 place annually and they consist of going this way from
6 place to place and back again. But these other things,
7 these eruptions, are movements that are unheralded
8 and do not seem to make any sense, they are sporadic
9 and irregular and one never knows what is going to
10 happen.

11 They are more pronounced in
12 the forest than they are up in the Arctic and then
13 they become conspicuous way farther south because
14 the birds pour out of the boreal forest with no
15 warning and descend on the southern mixed forests.
16 Mostly this involves small songbirds, sometimes
17 predators that move along with them, but it seems to
18 be a combination of factors, extreme climate which
19 you have got throughout that entire picture, enough
20 mat, extreme climate, extreme specialization in these
21 things in terms of their food and irregularity, un-
22 predictability in the fruiting success of the
23 fruit that they depend on and the way that it is
24 thought that these things happen and I suspect that
25 it is also the way things happen north of the trees.
26 The one year there might be really good, favourable
27 weather at nesting time, they get off a good hatch,
28 and you have a nice, unusually good, let's say, fruit
29 crop in the fall to fatten them up for the winter.
30 They get through the winter -- many, many more of
them survive in the course of the winter than normally

J.A. Livingston
In Chief

1 do and as a result of all of these things happening om
2 in tandem you get the population building beyond its
3 normal level. But usually you do not get two
4 favourable years in a row so the next year may be
5 distinctly unfavourable or perhaps just ordinary and
6 as soon as there is a poor year, away they come,
7 they are forced out looking for food and pour literally
8 all over the southern part of the continent in search
9 of food.
10

11 So the ultimate factor just
12 like it is in any migration, is food and again this
13 is reflected in the numbers of predators. So just
14 as these regular clockwork kinds of migrations are
15 solutions to the problems of food supply that
16 bottoms out every year, these irregular eruptions are
17 as responsive to the problem of food that bottoms
18 out on an unpredictable basis.

19 I think that these things
20 may be more widespread than we know at the present
21 time. You might speculate it applies to all species.
22 It is simply a magnification really of the undulations
23 that go on in population levels of all species anyway,
24 but in birds that are noted for population explosions
25 like that and collapse with emigration, I think that
26 it is quite common because they live in a habitat all
27 the way through the north here where imbalance is
28 not the exception, but the rule. Imbalance appears
29 to be the rule so far as these populations are con-
30 cerned in high latitudes and if we accept that imbal-
ance appears to be the rule in both the boreal

J.A. Livingston
In Chief

1 zone and the arctic, then we have to conclude that
2 these ecosystems retain such stability as they have
3 simply because it would be quite rare for some natural
4 perturbation to tip the balance when it is most
5 in balance. That would be a heavy coincidence,
6 but we do not have data to allow us to speculate
7 beyond that point really.

8
9 Now, I want to look at the
10 habitats, at the places in particular that are shown
11 on our map. I want to begin at the top. Dr. Bliss
12 started at the bottom, we will start at the top, with
13 the Yukon coast where you have ice and wind action over
14 time together with other things, producing along that
15 Yukon coast and Alaska coast this extraordinary complicated
16 series of gravel barriers and beaches and lagoons and
17 marshes and ponds and things like that that are
18 in turn related to the braided deltas that you have
19 seen of a lot of these north coast rivers.

20 Now, this complex together
21 with off shore islands, Herschel being the biggest
22 one, but there are a lot of small ones, too, supports
23 enormous numbers of birds for the purpose of nesting.

24 So having in mind the
25 well known low productivity of northern systems in
26 general this coastal complex is an exception and
27 an important one and I would describe it as one
28 of the oases that I was talking about earlier, where
29 if you move into the oasis really consisting of this
30 long coastal ribbon of apparently unusually highly
productive habitat in terms of birds. If you move into

1 the system a little more deeply, clearly unusually
2 high productivity in terms of the invertebrates
3 and the other organisms that sustain the birds in
4 of course
5 season -- not just breeding, but also/in migrating
6 flocks.

7 Now, this flags, as they say,
8 a major gap in our knowledge. In my knowledge any
9 way at the present moment. It is obvious that a
10 great number of birds are being supported by that
11 north coastal system. But so far as I know we
12 do not know very much about how it supports them and
13 we need to know that.

14 In other words, we know
15 very little of the system itself so far as it
16 relates to birds, that coastal system. Obviously,
17 it has something to do with production of a lot of
18 fish and a lot of small aquatic invertebrates, and
19 this must have something to do, at least in part
20 with this mix, a regime, a seasonal regime, I
21 suspect of salt to fresh to salt, through the
22 brackish ponds and lagoons that are there in the
23 course of the season and thenutrient flows at
24 the edge of the sea itself.

25 Presumably it is pretty
26 salt before the melt, presumably then it gets a lot
27 fresher, presumably again it gets a lot saltier
28 when the rivers dry up in the fall, I do not know,
29 that is just a guess, and one would imagine that the
30 productivity of the invertebrates is tuned into this
regime and that is the way that it works, that is

J..A Livingston
In Chief

1 the way that it turns out when you have this immense
2 productivity later on in the summer in August approx-
3 imately.

4 Anyway, that is an important
5 limitation to our ornithological knowledge at the
6 present time, we do not know how the birds fit in
7 to that system.

8 Now, along the coast there
9 are spits and islands as there are outside the
10 Mackenzie Delta and all along that are used by
11 species like the brant that I spoke about, eider ducks,
12 gulls and terns and things like that that like
13 to be protected from mainland invasion, and the
14 coastal sea and the little lagoons along, I will
15 show you a couple of pictures of it, are used by
16 three species of loons that fly there from tundra
17 lakes, ponds, to feed.

18 Then there are nesting
19 small short -- little, shore birds all along,
20 there are many, many kinds.

21 On the tundra as you have
22 seen and heard, despite its -- you know in a gross
23 sense -- its homogeneous appearance, the tundra,
24 the coastal tundra is a mosaic of kinds of tundra
25 with all kinds of special little habitat types within
26 it. Now polygons of a couple of sorts and tussocks
27 and wet and dry and all the rest and each has
28 specific birds attached to it. We can describe
29 these in terms of the birds perhaps more readily
30 -- much more readily than a mammalogist can identify

J.A. Livingston
In Chief

1 with these vegetative mosaics.

2 The rivers and deltas I think
3 in the foothills, we have seen, I do not think too --
4 we have seen in the earlier slides and I will show
5 you a couple more and ponds and lakes going through
6 again -- this is interesting, they produce an enormous
7 number of ducks, that are produced on these tundra
8 ponds and lakes, but some of them seem to produce
9 a lot of ducks and a lot of them do not seem to
10 produce any ducks and I am not quite sure what it is
11 it has got something to do obviously with the nutrient
12 flows in them, but some are good duck lakes and
13 some are not and this could use some perhaps further in-
14 vestigation. It is interesting and then one could
15 sort of concentrate on the good ones.

16 As you have seen, the north
17 slopes start to get very rolling and foothilly into
18 the mountains and so on and there are special bird
19 species related to that. The most -- the ones of the
20 most significance to us of course are the cliffs that
21 sustain these rare and endangered birds of prey,
22 the falcons and eagles.

23 The north slope is important
24 through the season. I want to briefly speak about
25 that because in the spring and fall it supports many,
26 many more birds than it even does in the nesting
27 season and that is a lot of birds because both spring
28 and fall you have got hundreds of thousands and I
29 would suspect perhaps millions of birds that pour
30 along that north slope complex in season feeding -- most

J.A. Livingston
In Chief

1 of them feeding as they go, and they are feeding
2 both in the water, in the salt water and in the
3 bracken pools and of course on the tundra.
4

5 In late summertime and I will show
6 you a couple of pictures of the sorts of place.
7 We have an enormous number of ducks that gather
8 in these places also for moulting in the flightless
9 defenseless period as I have already mentioned.
10 But the big time is in the fall, presumably
11 again when productivity has reached its peak that
12 you get these astonishing numbers of migrating
13 birds moving across in both directions according
14 to their target or according to where they came
15 from.

16 You have loons and swans
17 and geese and birds of prey, cranes and plovers and
18 ducks and sandpipers, the whole works pouring in
19 enormous numbers. One of the most notable things
20 for those of you who have not seen it is the migra-
21 tion of northern phalaropes which are pretty little
22 sandpipers like this, that come literally by the
23 tens of thousands in their flocks and they are
24 accompanied by jaegers and the jaegers go along with
25 them eating the phalaropes as they go and it is
26 quite a sight to see in august.

27 But nothing can compare on
28 that coast with the fall flight of the snow geese.
29 As I said they come at the end of summer to the
30 Mackenzie Delta and in that general area and then
they come out of the northslope by the thousands upon

J.A. Livingston
IN Chief

1 thousands of them, and they spread out all along
2 the coast and all along the slopes right up into
3 Alaska feeding on the vegetation as Dr. Bliss said,
4 fattening up, fueling up for the migration down the
5 Mackenzie Valley.

6 Now, as I said, it is a
7 critical phase of their life cycle because they are --
8 one might say ^{pooped} / after the nesting season -- it
9 may be that the female geese do not get to eat at all
10 during incubation and they have the enormous energy
11 drain of moulting. They have got a lot of work
12 to do in terms of putting on fuel while they
13 are sitting on the north slope at that time of year,
14 and so you have got snow geese in fact, probably from
15 Bank's Island from the Anderson River Delta, from
16 Kendall Island, adjacent areas in the Delta all in-
17 volved in this late summer feeding when they fly
18 across to the north slope. So this way -- you see,
19 we tie together the relationships of areas that are
20 lying long, long distances apart and one makes the
21 point that it is quite impossible from the ornithologi-
22 cal point of view then to treat any of these
23 areas in isolation because the geese are the mani-
24 festation of the relationship between them.

25 The migration across there
26 is complex and not understood too well, because as I
27 said, you have got birds moving in both directions
28 at once, not of the same species, but you have
29 got birds flying this way and that spring and
30 fall according to their goals.

J.A. Livingston
In Chief

1 So any way at different
2 seasons through this season from break up to the
3 first storms in fall, you have got this coastal
4 complex and the slope itself, supporting bird
5 populations according to species from Alaska,
6 from the Berring Sea, from the Pacific and populations
7 from the Mackenzie Delta and away on beyond to
8 Bank's Island and there is probably a relationship too
9 with the ducks of Old Crow, but I do not understand
10 that at this point.

11 Now, the Delta. It has
12 been calculated that the Mackenzie Delta, by the
13 people who measure such things that Deltas and other
14 estuaries like these little estuaries on the
15 north coast, rank on a world basis with the
16 arementioned coral reefs and tropical rainforests
17 in terms of being biologically productive ecosystems.

18 The north coast of the
19 Yukon is an estuarian complex and of course the
20 Mackenzie Delta is an estuary.

21
22
23
24
25
26
27
28
29
30

J.A. Livingston
In Chief

1 Just like any other ecotones,
2 estuaries are more productive than either the salt
3 water on the one hand or the dry land and the fresh
4 water drainage on the other. It's more productive
5 than either of those, or both of them in aggregate.
6 So, although they have many component parts, and coming
7 back to the business of coral reefs and tropic eco-
8 systems and diversity in component parts, estuaries
9 are exceedingly delicately balanced, so it would
10 seem, and susceptible to disturbance. Their resilience,
11 although we don't know anything about their resilience
12 in these latitudes, I emphasize, is probably very
13 severely limited and that's not said on the basis of
14 any Arctic evidence that I have, or sub-Arctic, but
15 rather on the basis of estuary evidence in other parts
16 of the world, and that's all I know about that.

17 Now, the seaward spits and
18 islands are important for generally the same sorts
19 of breeding birds that I mentioned earlier, for the
20 north slope, There are Sabine gulls out there, and
21 there are eider ducks and gulls and things like that,
22 and of course the brandt. They're safe from predators
23 and they're not afraid of birds of prey very much,
24 they can fend them off generally. Unless we give the
25 bird of prey an extra advantage, which we sometimes
26 do, if you kick a bird off its nest -- I mean flush
27 it off would be a better word, frighten it off its
28 nest, there will generally be a predator hanging
29 in the background ready to take advantage of that.
30 In fact, crows and ravens and jaegers learn to follow

J.A. Livingston
In Chief

1 you, and I've been followed by them and I've been
2 followed by Arctic foxes that learn to follow you
3 when you frighten birds that nest so they can get
4 what's there.

5 So these birds that are out
6 on these coastal things are safe from foxes and what-
7 not, but they're not safe from birds of prey unless
8 we give them freedom from disturbance. Now on the
9 tundra, the same kinds of things, in the tundra portion
10 of the delta I'm talking about now, the same kinds of
11 things that we talked about on the north slope, lots of
12 loons, lots of swans, three kinds of geese, many ducks
13 and cranes and shorebirds and all the rest of it.
14 It's loaded with birds, and no area in our region is
15 so productive save only the Yukon coast. Breeding
16 habits are both the same, and the species are about
17 the same, and I reckon the delta has the edge in terms
18 of numbers of species breeding there.

19 Now in the treed part of the
20 delta, it's really interesting, again from a technical
21 point of view because a lot of Boreal species have
22 their farthest north extrusion, as it were, in Canada.
23 Nesting species, there are swans all through it, ducks
24 and what-not.

25 I should say here apropos
26 the treed portion of the delta, that there is evidence
27 again in other parts of the world, that the vegetative
28 cover on the terrestrial portion -- the estuaries and
29 deltas -- is of critical importance. Apparently in
30 maintaining the ecological integrity of the system as a

J.A. Livingston
In Chief

1 whole, including the off-shore system.

2 With an early spring just a
3 seasonal account in the delta, in very early spring
4 there's an absolutely spectacular migration of eider
5 ducks coming from the Pacific. Along the south
6 shore of the Beaufort Sea and pouring past the delta,
7 and at that point they sit down on the leads in the
8 ice and rest and feed when they can, when there are
9 leads in the ice. A little bit later, again from
10 the west the brandts start coming from the Pacific
11 toward their nesting sites, as I've already mentioned.
12 By the end of May you've got a whole lot to birds all
13 nesting. You've got swans and snow geese and brandt
14 and that already on their nest by the end of May in the
15 delta, while others are still pouring through in
16 enormous numbers towards the east and the north.

17 There are a lot of loafing
18 areas, as we call them, in which congregate these non-
19 breeding things, moulting things, and later on after
20 the moulting is done, a lot of these sites -- and they
21 pin-pointed in the delta, we know where they are --
22 are used as staging areas again, pre-migratory fuelling
23 up bases. So here the relationships of the delta with
24 other western Arctic regions becomes absolutely
25 critically important, because essentially all that it
26 is, apart from the breeding things that are there, it's
27 a great big funnel that directs birds from literally
28 every point of the compass up there to and from the
29 Mackenzie Valley, according to the season, and the
30 direction of flight is species specific, season specific,

J.A. Livingston
In Chief

1 so that direct connections though through the delta
2 with Banks Island, with away over at the Anderson River.
3 the entire Liverpool Bay region and the north slope
4 of the Yukon and Alaska as well as the valley itself,
5 of course, and the prairies and all that beyond,
6 ultimately with Central and South America.

7 Now as we've seen, some
8 events ^{are} not as regular as migration, from time to time
9 we have drought on the prairies, as you well know,
10 and ~~when those drought years are~~ bad, the value of the
11 delta becomes even more extenuated as an insurance
12 area for producing ducks. It may force them to come
13 farther north to breed, and those that do breed by
14 the thousands in the delta, are what one calls a
15 breeding reservoir to keep that species in business
16 until the drought is over farther south. It also,
17 in an even more practical sense, today as more and
18 more of the prairies are being drained, prairie pot-
19 hole wetlands, for agriculture, the importance of
20 these northern nesting areas for ducks is becoming
21 greater, I would say year by year.

22 Now the valley itself I
23 don't think that we need to spend too much time on.
24 It's a bird migration corridor of world rank, as I
25 am sure you all know, and no estimate of the number
26 of birds in it would be possible. A lot of birds
27 also find nesting habitat here. Very important to
28 us, when considering the north and these other phenome-
29 non along the coast are the islands and bars, gravel
30 bars and little gravel islands in the river at various

J.A. Livingston
In Chief

1 points. Now these are used extremely heavily by birds
2 in the spring and fall migration. They sit down on
3 them to rest. Snow geese and swans literally cover
4 some of these islands in spring and fall.

5 Also again this timing thing
6 is so interesting. They're ready to lay the moment
7 they get to their colonies, the snow geese. We think
8 now that they may well breed, mate on these islands
9 so that they are already to drop that egg the second
10 that they get there, on banks and on the delta what-
11 not . There are in the river, in migration of course
12 masses of ducks and loons in season. But also there
13 are quite a number of lakes, as you well know, in the
14 corridor, in the valley of the river itself, lakes that
15 adjoin and run alongside the river. Then these are
16 used extremely heavily in migration by loons and ducks
17 and others, and they also provide nesting habitat for a
18 whole lot of things.

19 Way down, as we get farther
20 down of course there is a multitude of forested
21 lakes that contain the rare and the endangered bald
22 eagle, and the vulnerable osprey, both of which occur
23 through there in the woods, so in aggregate, in spring-
24 time the Mackenzie Valley fills a very, very high
25 proportion of the western Arctic with a very, very high
26 proportion of its breeding birds, from loons and
27 swans and things right through the whole taxonomic
28 order to finches and buntings . It's intimately related
29 obviously to the Old Crow Flats and the Yukon north
30 slope and the coastal complex, the delta and all the

J.A. Livingston
In Chief

1 rest of it, Liverpool Bay and banks to the east as
2 far as the Mason River, perhaps farther, I don't know.

3 Now as we're moving down
4 through toward the Boreal Forest, perhaps I should
5 have mentioned earlier, it's always easier for me anyway
6 to get a feeling for the north in the tundra and the
7 boreal woods by looking at a map with a north polar
8 projection, because ^{in the} then you get the pole/centre, you
9 get the ice cap around it, and the ocean around it,
10 and then the tundra around it, more or less concentric
11 circles, and the final concentric circle of course
12 is the enormous mantle of spruce and fir and larch
13 that hang there right around the globe, the circle
14 of Boreal Forest. This is going to sound dreadful
15 to Dr. Bliss, but an ornithologist can get away with
16 dividing it into six habitat types, or six sorts of
17 things that one can characterize in terms of birds,
18 and I would call these muskeg, coniferous forests,
19 mixed and deciduous forests, scrub, marsh and lakes,
20 and these are really gross categorizations, they could
21 be divided much more finely. Essentially, you see, just
22 like the tundra, this Boreal zone -- I'll use the
23 word again, it's been used before -- is indeed a mosaic,
24 it's a mosaic in successional stages, that is quite
25 specific, different vegetative associations, different
26 age, and different composition.. Most of these, you
27 see I think it's possible to characterize without stret-
28 ching it too far in terms of their predominance in the
29 more conspicuous breeding bird species, so we tend to
30 describe them from the birds that are there rather

J.A. Livingston
In Chief

1 than from association of plants themselves. But most
2 of these alien characterizations would involve small
3 birds, birds you never heard of really, and also ones
4 of such enormous continental distribution and enormous
5 absolute numbers as a result, that they wouldn't be
6 of much practical value in the present context so we
7 don't need to talk about them too much. In other words,
8 what I'm trying to say really is the boreal zone is
9 so big, it's so vast, that on a gross scale it's so
10 homogeneous that the bird student is much more
11 concerned after all with rare and endangered and
12 threatened and vulnerable species than he is with
13 the multitude of little birds that there are there.
14 That of course is what we tended to do over the past
15 five or six years' work.

16 The rare and endangered species
17 that are in those areas, with the exception of the
18 whooping crane, which is down, you know, in the Hay
19 River area, are all birds of prey. They are falcons
20 and eagles, as I've already mentioned, and these
21 problems then are quite specific. The birds tend to
22 use the same nesting sites year after year after year,
23 these can be pin-pointed and these are known; but less
24 critical ones, things like loons, vulnerable though
25 on lakes, are all through, and so are the ospreys.

26 Very quickly, south of 60
27 degrees, the boreal zone goes well south of 60,
28 as you know, but pretty soon you're into the aspen
29 parkland that we saw and the prairie country, pot-
30 hole country pretty well impacted by ourselves over

J.A. Livingston
In Chief

1 many, many years, and areas of particular importance
2 with regard to birds, you could pin-point quite
3 quickly. There are the migration stop-over points,
4 the resting points for birds that rest up in the
5 Arctic or sub-Arctic, involved here. These are pretty
6 regular and one knows where they are. Loons and swans
7 and geese and ducks and some birds of prey, whooping
8 cranes and sandhill cranes and all kinds of shorebirds.

9 There are other areas that
10 are important for locally nesting species down south,
11 things like loons, white pelicans are very important.
12 Trumpeter swan, which is another case.
13 Canada geese are all over, prairie ducks, birds of
14 prey, grouse, cranes, all kinds of things. Many of these
15 have relatively little optimum habitat left to them
16 nowadays. Then of course, we have areas that we
17 know are important for critically endangered species.

18 Finally down south of 60 there
19 are, as ornithological there is a special
20 interest as residual remnants of original natural
21 communities as opposed to the breeding sites of parti-
22 cular species of birds. Natural communities like those
23 involving prairie chickens, sage grouse, long-billed
24 /curlew, burroughing owl, are all getting to be in increasingly
25 short supply, so that would be a way that one would
26 characterize, I think, ornithological interest or
27 concern south of 60.

28 I want to recap, before I
29 finish I want to recap these several zones that
30 I've gone through so horrendous^{ly} quickly with some
pictures. Forgive me if some of them are redundant.

J.A. Livingston
In Chief

1 Obviously we've been, Bliss and Jakinchuk and I have
2 got our photographs in the same places so I'll whip
3 through the ones that are identical and I'll try and
4 call attention to those that may give some little
5 information, so if we could have the slides, thanks.
6 Can we shut that down? Thank you.

7 This is a picture of this
8 estuary lagoon system along the north coast of the
9 Yukon. This is a contained water body, you can see
10 the gravel beach and all that, and in there is going
11 to be very changeable in terms of its salinity, it's
12 going to be different in terms of its productivity
13 than the sea is to the outside. This is one of these
14 areas that's so important., I think. This is a perfectly
15 appalling picture technically, but still I think it
16 shows what's needed.

17 This is Herschel Island on
18 the north.

19 THE COMMISSIONER: Could we
20 see these better in other lights? I think someone
21 has gone to turn the lights off.

22 A Thank you very much.
23 That's much better. It's a bad shot but it's Herschel
24 Island on the north coast of the Yukon, as you know,
25 and this is the extension along here of one of those
26 very, very long spits that I talked about. Finally
27 the spit disintegrates into little islands, and on
28 the islands of course you have these birds nesting that
29 I was talking about. This barrier, as it were, contains
30 freshish, brackish water in here and is tied in, of

J.A. Livingston
In Chief

1 course, into the braided gravel belt of some of
2 these north slope rivers. Here on Herschel you can
3 see this giant bay here at the southern edge of it,
4 and in here, this is used by thousands and thousands
5 of scoters, which are diving ducks, during their
6 flightless moult, and all along here you've got
7 birds in flight with moult, and this is one of the
8 richest systems, I reckon, in the entire Arctic.

9 The same thing, the water
10 being contained in here getting gradually saltier in
11 the course of the summer, loons feeding like mad
12 all through here. Incidentally reference was made,
13 somebody was talking about bowhead whales in the old
14 encampment. There is a very interesting historic
15 encampment at the end of this little lagoon here
16 with all the former skulls of former bowhead whales
17 and things like that in the lagoon still since the
18 turn of the century, I suppose.

19 Forgive me for the caribou,
20 it was just an accident, but this is to show this
21 complex again of very peculiar and very particular
22 water conditions that occur and produce certain kinds
23 of life that aren't replicated inland on the tundra.
24 Once again it's that same coastal system.

25 Now you have little sedge
26 marshes and things occurring here that you don't
27 get any place else, and that's the open ocean of course
28 beyond, some ice out there.
29
30

These are the Phalaropes that come in the fall by the tens of thousands, scores of thousands along the North Coast. And these are they again. Loons, as I say, we have 4 species; the Common Loon is the least common, sometimes gets up to this coast but not often, it is at the base of the delta however, this is the Arctic Loon, which has to have these coastal waters for feeding when it's nesting inland on the small lakes. These are a couple more out on the ice pack that hangs along that shore mostly all summer long. In some years it stays there for good. Nothing-- just to show the yellow-billed loon which is the rarest of them all, the one perhaps most critical. Rather narrow habitat requirements in small tundra pools. Glaucous gulls nest on those spits and islands that I showed you. Thayers gulls stand on propane tanks. This is a part of an enormous migration of birds, but it's not really a migration, you've got a constant movement along that coast all summer long, back and forth with either -- these are Brants I guess on their way westward in August, but you've got Scoters moving both ways, duck\$ of all

In Chief

1 kinds all summer long. These are Brant going back
2 west to the Pacific. Eider ducks going back and forth
3 all the time just to give you a feeling of what is
4 moving there and the movement never really stops. It
5 must be extraordinarily rich but I say that just as a
6 conclusion rather than anything else. Now, so much for
7 the coast, this is the North Slope, this is the Firth
8 River at the 15th of May. The little tussocks are
9 just beginning to show and the migrant birds are already
10 there, a very few of them pioneering males setting up
11 nesting territories. Small birds long spurthings like
12 that. And gradually-- now these will almost be on
13 territory by now, so that they can lay by at least by
14 the first of June so that they can hatch by at least
15 the 15th of June, so that you work everything backwards
16 from there and this is what the thing looks like when
17 it starts to produce young birds, this is around the
18 Firth River I think, this picture. When it starts to
19 produce young songbirds and the young shorebirds are
20 about to emerge. The tussocks of course are used by
21 the birds. You've got little microclimates under them
22 some wet, some dry, birds very specifically adapted to
23 these kinds of habitats. Some small songbirds nesting
24 up underneath some sandpipers and grouse, and ptarmigan
25 sitting in the lee of them. This is the wimbrel
26 is a curlew that you get in both wet and dry tundra
27 right clean across the tundra edge, right across the
28 country. That picture was not taken on the North
29 Slope, it was taken at Churchill, Manitoba, but it's the
30 same situation.

In Chief

Golden plover in the really dry. You can see it's lichen, there is lichen in this tundra and the really dry stuff and that's what they prefer. It's nest, golden plover. In the shelter it may have a bit of tussock, but usually they are on quite flat ground and they are not into those tussocks. Just to show the so-called broken wing act, which is simply a response to fright, that they go through, the effect is to get you away from the eggs.

In Chief

1 Again the tussock slope and
2 flattening out into a flatter tundra type with the
3 mountains in the distance. This sustaining quite
4 a variety of bird habitat is the point, it's the
5 mosaic has already been described and I won't go over
6 that ground again. You can see how lush it is in early
7 summer, here are the willows in flower.

8 Now these are very important,
9 and I'm only beginning to comprehend how they work.
10 These are the braided windings, dried up rivers and
11 such as the Malcolm river delta on the north Slope.
12 Now, in the spring this is of course full of water later
13 on in the fall, but there are little pools and
14 adjacent to this there are some of these little wet
15 sedge marshes and in there there are a couple of species
16 of sandpipers that I find breed, but then when the
17 young are ready to come out, and come out and feed in
18 the open the water in this turns out to a fall,
19 just the right distance, a little bit, not as dry as this,
20 and they are specifically timed, it's the most extra -
21 ordinary thing, that they come out when they are still
22 little bits of water, little bits of invertebrate in it
23 at just an exquisitely timed moment to feed those young
24 birds. It's most fascinating.

25 This is a fox den. I didn't
26 put it in for that reason, but I'll just mention that
27 it is and you can see the lushness of the vegetation
28 just as Mr. Jakinchuk indicated. You can spot them
29 from a mile away. Those empty ones are just ---

30 Here is the rolling kind of

In Chief

1 tundra. Back in here, now these are those sort of
2 medium sized lakes in which we get Artic Loon breeding
3 but they will fish out some of these smaller lakes
4 very quickly and have to come to the sea. This is
5 emphasizing the narrowness -- I'm standing here only
6 about two hundred yards from the sea and this is how
7 close the mountains are on the North Slope and pinched
8 the migration of these animals is.

9 Ptarmigan are everywhere.

10 I've seen them right in the water, this one is in quite
11 a wet spot, I mean nesting, virtually in the water and
12 right on the driest possible place, so they are all over.
13 I'm happy to report on the human disturbance factor
14 with regard to the ptarmigan. It's eggs however are
15 not immune and one doesn't put the bird off the nest
16 if one can help it because the jaegers will get it.

17 Now the great sight on the North
18 Slope in the fall is the arrival of the Snow Geese and
19 there they are, the latter part of August, toward the
20 end of August. And I have no idea how many birds there
21 are in these photographs, but this is the way it looks
22 at the end of August. And these have come all the way
23 as I have said away to the east. A lot of birds, but
24 remember it's all of this western Artic population,
25 again I emphasize that. Not all there at once, clearly
26 because this thing goes on all through until October,
27 and they are leap-frogging around.

28 Now, into these little rivers,
29 back into the foothills in the mountains, this is the
30 Trail River which some of you know and there is the

In Chief

1 nest of a rare gyr falcon up here, that was really the
2 thing. You can see the willows down at the bottom and
3 this supports different sorts of birds than you get up
4 on top of the tundra, but they are songbirds, they are
5 only of moderate interest to you.

6 Again the rising and falling
7 of water is ~~timed~~ it seems, or rather the birds are
8 timed with it in terms of their nesting and delivery
9 of their young. This is the Firth River, caribou in this,
10 I think it's the Firth River, ~~no there~~ are the caribou,
11 there are a couple of caribou swimming here somewhere
12 along, it's almost the same shot that we ~~saw~~ that we
13 saw earlier.

14 Banks, again to illustrate
15 the point, this has all been done so I'm just going to
16 go right through them, you've seen them all already.
17 These kinds of places are of critical importance. Most
18 different birds of prey, that's what we are concerned
19 about when we get up into the foothills and we begin
20 to get into the mountains. This is the Crow River.

21 The delta itself. That's in
22 May, but it's starting to break up very quickly. The
23 complex you've already seen, I won't -- this is
24 interesting, again, for the birds for the timing of the
25 arrival of the birds around the beginning of June
26 because you've got open water over ~~here~~ but not here, and
27 habitats are ready for some species and not ready for
28 others, so you've got an interesting sort of leapfrogging
29 of the birds into appropria_te habitats, and they all
30 seem to follow one another at very closely timed intervals.

In Chief

1 That's the sea ice coming apart.

2 Here -- I don't know if you
3 can see them I hope you can, two white spots, these
4 are mated pairs of the birds, have already arrived, mated.
5 There's a flock, another flock, these are snow geese.
6 These birds are already mated and right on to their
7 nesting. This is a gang of non-breeding swans. The
8 swans that are breeding are already on their nesting
9 site. These are the ones that won't breed this year,
10 they'll hang together in crowds like that in a habitat
11 that they would never occupy during the nesting season.
12 So that's the business about multiplicity of habitat
13 types and requirements.

14 The polygons I don't need to
15 go on about, you've already seen them, as I say there
16 are specific edges of the polygon provides nesting bird
17 habitat. More flocks of white birds, the delta melting,
18 The treed part of the delta; this is really swan country
19 and duck country. This, down at Norman Wells to make
20 this point about islands in the river that are used by
21 the Snow geese, the, of course the great cliffs on some
22 of the nearby mountains, and the fact that there are
23 lakes and so forth as I mentioned earlier alongside in
24 the valley that are heavily used by migrating birds.
25 Again the corridor itself, illustrating sites for
26 endangered species of raptorial birds. The small lakes
27 and marshes that both produce nesting birds that are
28 migration corridors and that make the big migration
29 corridor itself. And here are all these ponds that
30 haven't melted yet. And these produce enormous numbers

In Chief

1 of birds and are also migration stopovers. This is
2 a classic site for a golden eagle or a peregrine
3 falcon.

4 That's all the slides. I just
5 want to say a word because my colleague Mr.
6 Jakinchuk expressed his concern about the semantics
7 and the difficulties of having to deal with rare and
8 endangered species and I simply want to echo some of the
9 things that he said, because no, obviously no species
10 is immune to human activity, to the effects of it.
11 But because these things vary in abundance from place
12 to place and that's the real problem, and they also
13 vary in the extent of their resilience to things, you
14 can't really confidently categorize them, as to their
15 survival potential. Now, I don't suggest that there
16 are any absolutes involved in what I'm saying now, but
17 I do suggest four categories and we've discussed these
18 lots of times and in, my colleagues and I, but for four
19 categories for bird species anyway and these I would
20 call critically endangered, endangered, rare and
21 vulnerable.

J.A. Livingston
In Chief

Critically endangered species such things as the whooping crane, you know how many there are, you know they're on the edge, you know all about it demonstratably, almost extinct. There are other species in that category that may still occur in that area, and that is the Eskimo curlew. It was considered extinct for many, many years, and then it reappeared, it's been seen around by a few people. There may be some up somewhere around the Mackenzie Delta. Those would be critically endangered.

Now endangered species would be something like the ^{peregrine} falcon that's been exterminated now over almost all of North America and Europe, but it does have a cosmopolitan distribution. It's spotty but it is around many many parts of the world. It's going down, but we don't know how many there are. It may be fairly healthy somewhere, but nobody knows that.

Now this species, the peregrine disappeared from most of North America before we even knew it. It did it right in front of our eyes and we didn't even see it happen. So you can have a species moving from the rare category to the endangered category with horrifying speed, and no warning, and usually you make your judgments as to the way you categorize it after the fact. I simply say this because a species can slip and it can happen virtually while you're watching, and other things in this category are the two eagles, the golden eagle and the bald eagle. Now I would say a rare species^a thing like

J.A. Livingston
In Chief

1 the mysterious bird I mentioned earlier, the Hudsonian
2 godwit which is known to be breeding in a couple of
3 scattered treeline places, but whose absolute numbers
4 are not known, but it's clearly going downhill. As I
5 say it can slip into a higher category rather easily.
6 I would also say another rare species would be the
7 gyrfalcon which occurs right around the world, in circum-
8 polar regions but it's exceedingly rare everywhere, it
9 is no place common; and of course the trumpeter swan
10 I've already mentioned. But the real one, the tricky
11 one is the vulnerable category, that is really a value
12 judgment, a judgment ^{call a selective} sort of thing, it's hard.

13 You see, a vulnerable species
14 is more difficult with birds really, although I don't
15 think that Ron thinks it is. Maybe not. This would
16 include something that isn't ^{yet} threatened necessarily,
17 but one that you know is so specialized in some way,
18 whether in food or nesting habitat, behaviour, wintering
19 ground, or something else, that some environmental
20 change would affect it seriously.

21 A historic example of these
22 are legion. The passenger pigeon, not because people
23 shot it, but because it depended on open beech forests
24 or the eider billed woodpecker, not because people
25 shot it but because it had to have mature cyprus
26 trees, and things like that.

27 The buff breasted sandpiper
28 because it has to have well-drained tussock slopes,
29 I don't know, but that's what I would say about
30 vulnerability. Now obviously you could make a case

J.A. Livingston
In Chief

1 for virtually any species on these ^{speculative} grounds,
2 but there are some, and I would say the loons, all
3 four of them are indeed vulnerable because they're
4 susceptible to disturbance and susceptible to the
5 chronic effect of toxic chemical residue.

6 The rarest one, the yellow
7 bill, is restricted, as I said earlier. The white
8 pelican, much diminished breeder area in Western
9 Canada, it's not here on our map it's ^{farther} south, but
10 it's in the general area. There's danger to it also
11 from toxic chemicals.

12 Whistling swan, lots of them
13 as we saw in the pictures, but they're all in the
14 delta, in our area, in the region under enquiry here.
15 They're all in the delta, and they're vulnerable at
16 moulting time.

17 THE COMMISSIONER: Excuse me,
18 professor, you mentioned the pelicans and you said
19 they and others you'd mentioned earlier were in danger
20 from what, toxic chemicals?

21 A Yes, chemical residues
22 of various kinds.

23 Q The result of what?

24 A Oh, pesticidal residues
25 in the main, but not entirely, There are other con-
26 taminants that derive from plastics apparently that
27 are not fully understood, and some people think the
28 pesticides may have taken more blame than they should
29 have for things such as polychlorinated bi/^{phenols} in the
30 atmosphere, and so on. These things build up in the
food of the birds, it affects the thickness of their

J.A. Livingston
In Chief

1 eggshells, and we lost the brown pelican virtually
2 everywhere because the egg, this embryo can't develop
3 in the egg and the shell collapses. This is what
4 happened with the bald eagle and the peregrine falcon
5 and two or three others. Mostly fish-eaters, because
6 fish are able to apparently subsist at a sub-lethal
7 dose, and pack away a great deal without affecting
8 them. But it's magnified in the animal that eats
9 the fish, and it's the fish-eaters that have gotten
10 this particular problem more heavily than other birds
11 have.

12 As I say, birds concentrate.
13 The Pacific brant is vulnerable to flooding. That
14 could be vulnerable. Snow goose, anything we have
15 great numbers of birds in a very few places, you know
16 where they are, there are a lot of them, obviously they
17 are vulnerable if those places change. Ducks and other
18 sand groups. Birds of prey I've already spoken about,
19 and all the rest, these are just examples. But we do
20 have, I think you could come up with a good 20 or more
21 species in our region which have such specializations
22 whether it's in food or other demands, that one could
23 say that they are vulnerable. It's a category we have
24 to think more about.

25 We would ask, Mr. Commissioner,
26 to talk about birds and other wildlife ^{as} resources, I
27 would do so only briefly because since prehistoric
28 times the indigenous peoples in the north have made
29 use of local bird production, most waterfowl, I guess,
30 and grouse, but when you have in mind the rapidity

J.A. Livingston
In Chief

1 of social change, cultural change nowadays, it's not
2 possible for me at any rate to guess whether the need
3 for wild birds' food is going to persist for very
4 long or for how long. I just don't know that.

5 Clearly that's a legitimate
6 application of the word "resource" to birds, so long
7 as ^{application of some} ~~new~~ new kind of technology, bird-catching technology
8 doesn't change the dynamic between human use and bird
9 reproduction; but beyond their use by indigenous
10 peoples as a food base, I don't think -- this is
11 purely an opinion and it has no more scientific
12 merit than that. I don't think that the term "resource"
13 as applied to birds really fits somehow, because recrea-
14 tional killing, you see, of birds, as we practice it
15 in the southern part of the country, would be a different
16 thing in the north because the spring kill obviously
17 eats into breeding capital, and that says it. With
18 a fall shoot of birds would bring about a disturbance,
19 I'm not thinking about the number of birds that would
20 fall before the guns, I'm thinking much more of the
21 disturbance ~~factor~~ to these birds when they're in this
22 critical feeding, fuelling up staging periods, when
23 the stress already is great, as I've indicated earlier.
24 This would be one thing that one would be concerned
25 about, I think.

26 In summary, then, very few
27 generalizations are feasible for us. As you go up the
28 higher latitudes you get fewer bird species. In the
29 Arctic you get also lower populations as a result of
30 the capacity of support of habitat. Birds tend to

J.A. Livingston
In Chief

1 concentrate in relatively few and relatively small
2 areas of high productivity. The edge effect, both of
3 the sea and around water bodies, ^{and other places} is characteristic.
4 Northern biologic systems are comparatively simple
5 short food chains and all that. **Noted** for their
6 instability or at least their tendency to fluctuate
7 involving population cycles to some extent, and very
8 irregular population eruptions. Estuarine systems,
9 like the Yukon north coast and the Mackenzie Delta,
10 are of fundamental importance because they support
11 bird populations at various stages in their life
12 cycles through the seasons. Critical times for birds
13 are of course spring migration, incubation, moulting,
14 fall staging and feeding, and autumn migration.
15 Because these periods the energy demands are intensified
16 and birds are vulnerable to stresses of various kinds.
17 From the ornithological point
18 of view, it's impossible to separate ^{out the} Yukon north
19 slope then, and the sea coast, the Mackenzie Delta
20 areas to its east and to its north-east, or the Macken-
21 zie Valley for that matter, as individual phenomenon
22 in isolation from each other because they're all connec-
23 ted, they're all intimately connected, as I told you
24 with the geese and many more. It is suggested then
25 that in addition to critically endangered, and rare
26 bird species, that consideration should be given to
27 the official identification of those species which
28 because of their specialized needs, are vulnerable to
29 environmental shift.
30

Northern birds are seen as

J.A. Livingston
In Chief

1 in my opinion
resources ~~only~~ insofar as northern indigenous peoples
2 have a continuing need for this food source.

3 Thank you.

4 THE COMMISSIONER: Thank you
5 very much, Professor, for sharing your knowledge and
6 experience with us.

7 MR. SCOTT: Mr. Commissioner,
8 that completes the evidence of the living environment
9 except for two further witnesses which we propose
10 calling. The evidence of the two remaining witnesses
11 will last in total approximately an hour and a half.
12 Now if it would suit your purposes, to adjourn briefly
13 and call them now, or would you have us adjourn until
14 the morning?

15 THE COMMISSIONER: We'll adjourn
16 for 10 or 15 minutes and then we will carry on.

17 MR. SCOTT: Thanks.

1 (PROCEEDINGS RESUMED PURSUANT TO ADJOURNMENT)

2 MR. SCOTT: Mr. Commissioner,
3 yesterday Mr. Anthony for the Canadian Arctic Resources
4 Committee and some of his colleagues, including Mr.
5 Bell, who is here this afternoon, raised the question
6 of the role of the Department of the Environment at
7 page 915 of the transcript yesterday, and I made a
8 response indicating the steps that I proposed to take
9 in view of his request.

10 Following that, and as I
11 promised, I wrote to the Honourable Jean Sauve, the
12 Minister of the Environment, and because of the diffi-
13 culties of mail communication I telephoned the letter
14 to the Minister's office. The letter reads:

15 "Dear Madam Minister:

16 I am writing to you in my capacity as
17 Commission counsel to the Mackenzie Valley
18 Pipeline Inquiry which began its formal hear-
19 ings in Yellowknife, N.W.T. on March 3, 1975.

20 At the opening of the Inquiry, certain of
21 the major participants expressed concern about
22 possible constraints which might affect the
23 ability of government scientists and other
24 experts (and particularly those in your
25 Department) to provide the Inquiry with the
26 benefit of their expertise.

27 On March 4, 1975 and as a consequence of
28 this concern, counsel for Canadian Arctic Re-
29 sources Committee applied to the Commissioner
30 for an order directing me to seek your advice

1 as to the availability of your Departmental
2 experts who have relevant evidence to give
3 to the Inquiry.

4 In replying to this application I was
5 able to advise the Commissioner of your
6 decision, reported in the Toronto Globe &
7 Mail of Friday, February 28, 1975, to put
8 Departmental experts at the disposal of the
9 Inquiry and to open all doors on environmental
10 information and expert knowledge held by the
11 Department. At the same time I undertook to
12 the Commissioner to communicate with you to
13 accept this invitation on behalf of the Inquiry
14 and to indicate my desire to work out with you
15 and your officials the ways in which this
16 information and knowledge can most promptly
17 and efficiently be made available to the
18 Inquiry. I undertook to report to the Inquiry
19 the results of this communication.

20 Needless to say, I would be pleased to
21 meet with a representative of your Department
22 as soon as possible to make these arrangements.
23 Perhaps I could take the liberty of calling
24 your office to discuss a mutually convenient
25 time and place. Now that the Inquiry is under
26 way I am most anxious that the relevant evidence
27 of your Departmental experts be placed before
28 the Commissioner at the earliest opportunity,
29 not only in discharge of my undertaking of
30 yesterday to the Commissioner, but also to

1 ensure that as far as possible the Commissioner
2 is able to complete his work expeditiously and
3 with the assistance of the best expertise avail-
4 able.

5 May I say in advance that I am most grate-
6 ful for your co-operation with the Inquiry and
7 I look forward to meeting with you or your
8 officials in the very near future."

9 And that letter was signed by me.

10 I may say, Mr. Commissioner,
11 that I have now communicated with Mr. Jean Lupien
12 the Assistant Deputy Minister of the Department of the
13 Environment, who has affirmed to me that the Department
14 of the Environment will co-operate directly with the
15 Inquiry through Commission counsel and will make
16 available all studies and reports within the Department
17 not protected in the usual way by privilege.

18 Mr. Lupien has also specifi-
19 cally confirmed that his Department will assist in
20 making immediate arrangements so that the authors of
21 those reports and studies insofar as they are govern-
22 ment servants, are available to be interviewed by me
23 with a view to being called as witnesses, if their
24 evidence should be relevant and desirable.

25 A second point I wish to
26 make, as a result of the conversation with Mr. Lupien
27 Mr. Goudge and I will go to Edmonton on Monday and
28 meet with Mr. Jack Etoch, the Chairman of General
29 Services, the Director of the Environmental Protection
30 Services for the Canadian Northwest of the Department

L.D. Doran
In Chief

1 of the Environment. Mr. Lupien has advised me that
2 he will attempt to arrange the attendance at that meet-
3 ing of a senior assistant deputy minister of the
4 Department of the Environment from Ottawa, and Mr.
5 Alexander, general counsel for the Department.

6 Speaking for the Inquiry
7 staff, that is Mr. Goudge and myself who will go to
8 Edmonton, the purpose of that meeting is to see to it
9 that all the witnesses in the Department of the
10 Environment who have evidence to give will be
11 brought before this inquiry at the appropriate stage.
12 I'm sorry Mr. Anthony isn't present, but I've no doubt
13 that his perusal of the transcript will reveal that
14 those meetings are going to take place, and of course,
15 Mr. Commissioner, I will report next week as to the
16 results^{that} that meeting produces.

17 THE COMMISSIONER: Thank you,
18 Mr. Scott.

19 MR. SCOTT: The next overview
20 witness is Mr. Doran.

21
22 LEE D. DORAN, sworn:

23 THE SECRETARY: Will you
24 state your full name, please?

25 A Lee D. Doran.

26 DIRECT EXAMINATION BY MR. SCOTT:

27 Q Mr. Doran, I understand
28 that you are a B. Sc. from McGill University?

29 A That is correct.

30 Q An M. Sc. from McGill?

L.D. Doran
In Chief

1 A That's right.

2 Q And you are in the course
3 of Ph.D. thesis work at Dalhousie University.

4 A That's correct.

5 Q By whom are you now
6 employed?

7 A I am the president of
8 Lee Doran & Associates Limited.

9 Q And what is your dis-
10 cipline?

11 A We study the ecology
12 of water, aquatic ecology.

13 Q I see. Before forming
14 your company, what occupations did you pursue in this
15 field?

16 A As a consulting ecologist
17 on the staff of F.S. Sweeney & Company.

18 Q Yes?

19 A And graduate student
20 doing research in the West Indies and Eastern Canada
21 as well.

22 Q And I understand, Mr.
23 Doran, that in the course of your experience you have
24 worked on projects relating to the effect of hydro-
25 electric developments, pipelines and highways on
26 aquatic resources in British Columbia, Saskatchewan,
27 the Northwest Territories and the Yukon Territory.

28 A That's correct, yes.

29 Q And that your experience
30 includes the design and supervision of field studies

L.D. Doran
In Chief

1 on fishes and aquatic invertebrates.

2 A Right.

3 Q Analysis of data and
4 preparation of technical reports?

5 A That's correct.

6 Q And I also see -- I
7 won't trouble you or the Commission with it -- but
8 you belong to all the appropriate fish clubs.

9 A That's right.

10 (LAUGHTER)

11 Q Well now, Mr. Doran,
12 will you carry on, please, as the other witnesses have
13 done?

14 A Thank you.

15 Mr. Commissioner, ladies and
16 gentlemen, good afternoon. If I could have the first
17 slide then perhaps we could dim the lights, I would
18 like to begin by reviewing what Chris Hatfield and
19 myself will cover here this afternoon. We hope this
20 will provide a series of sign-posts to punctuate our
21 talk as we review the water system of our study area.
22 I shall begin by reviewing the characteristics of the
23 three main drainage areas under consideration, namely,
24 the Mackenzie, the Yukon, and the north slope of
25 Beaufort Sea watersheds.

26 Comparisons between the
27 watersheds should help to point out the significant
28 differences between them. Then I will talk about how
29 water areas work biologically.

30 No. 2, the aquatic systems
of the region.

L.D. Doran
In Chief

1 We will step back a bit from our
2 study area to consider the importance of various kinds
3 of aquatic habitat. Then we will see how the different
4 kinds of habitats work within our study area. An
5 important consideration throughout will be how the
6 waters of the area produce fish.

7 I will close by trying to put
8 these northern aquatic systems into a larger context.
9 Some discussion of more southern areas, as well as other
10 northern areas, should help to do this. In
11 addition, I will try to sneak through the academic and
12 popular battle lines drawn over the question of the
13 fragility of the Arctic and the stability of Arctic
14 aquatic systems. If I am lucky enough to emerge un-
15 scathed, I will attempt to look at our present state
16 of knowledge on the ecology of aquatic systems in the
17 area. Some gaps in our understanding of how the
18 systems work may become clear at that time.

19 Chris Hatfield will continue
20 by presenting the perhaps more immediately important
21 information on the fishes of the three watersheds. He
22 will talk about the kinds of fishes, their foods,
23 migration patterns, and spawning, nursery and over-
24 wintering areas. Chris will then review in some
25 detail the way that the people of the area use the
26 fishes. Next he will consider some important questions
27 about how critical the physical resources of the area
28 are for fishes. And finally Chris will summarize the
29 main points of our discussion about the water systems
30 of this northern area.

L.D. Doran
In Chief

1 I hope you have noticed that
2 we are going to insist upon talking about watersheds or
3 drainage areas. This is a consequence of the perhaps
4 obvious fact that water flows. It means that the
5 medium in which all aquatic activities take place --
6 namely water -- usually is going somewhere else. At
7 different times of the year or under different climatic
8 conditions, there can often be quite different amounts
9 of water moving. Yet the primary characteristic of
10 aquatic systems is maintained -- water flows.

11 As a result of water moving
12 downhill, things that are suspended in it or floating
13 on it will move along with it. To understand why there
14 is a given amount of silt in a water sample from a
15 point on a river requires an understanding of soil
16 conditions upstream. The effects of the soil condi-
17 tions at that point will be noticed downstream along
18 with the effects of everything else upstream of that
19 point. So to understand what is happening at any
20 point in an aquatic system, you must consider the
21 whole watershed upstream of that point. Watersheds are
22 our study unit.

23 The fact that water flows
24 downhill creates special problems for the organisms
25 that live in flowing water systems. It is easy enough
26 to move downstream by floating passively and letting
27 the water carry you along.

28 If you are very small, such
29 as the little organisms that live in stream gravel
30 or even a tiny fish, or if you are a plant -- a small

L.D. Doran
In Chief

1 microscopic plant with no powers of movement -- you
2 may have little choice. The bugs and the small fish
3 can seek out quiet waters, such as side pools or sloughs
4 and stay there until they grow big enough to swim
5 upstream. The plants, like the silt, however, are
6 more or less at the mercy of the flowing water.

7 In general, the animals that
8 live in flowing waters have adapted their life cycles
9 to that environment. Many of the bugs that live in
10 stream bottoms avoid the problem very neatly by moving
11 upstream in the air. They live for periods of up to
12 a few years in the stream bottom, growing bigger by
13 stages and slowly drifting downstream. They are
14 dislodged periodically, drift a short distance and sink
15 to the bottom again. As adults, they emerge from the
16 stream, fly upstream, mate and die. Their progeny
17 begin the cycle again in the upstream waters.

18 THE COMMISSIONER: Excuse me,
19 Mr. Doran, would you go back about 60 seconds? I was
20 writing something and I missed this last passage.
21 Forgive me, my apologies.

22 A I could begin where we
23 began talking about how animals adapt to this environment.

24 Q All right, that's just
25 where I dropped out.

26 A O.K. I was saying that
27 the animals that live in flowing waters have adapted
28 their life cycles to that environment.

1 The organisms that live
2 in stream bottoms avoid the problem very neatly by
3 moving upstream in the air. They live for a period
4 of up to a few years in the stream bottom growing
5 bigger by stages and slowly drifting down stream.
6 They are dislodged periodically, drift a short
7 distance and sink to the bottom again. As adults
8 they emerge from the stream, fly upstream, mate
9 and die. Their progeny begin the cycle again
10 in upstream waters. Indeed the headwaters of
11 streams themselves are important source areas for
12 keeping the downstream areas supplied with drifting
13 bottom fauna.

14 The fishes of flowing water
15 systems do adapt by growing bigger downstream, as
16 large fish and within the range of flows to which the
17 fisher adapted movements upstream are mainly a
18 question of swimming. Spawning migrations are
19 particularly common upstream movements of fish.

20 Since the adults do the work
21 of getting upstream the progeny need expend little
22 energy to reach downstream feeding or nursery areas.
23 They can just drift to the flowing waters. After
24 they grow large enough to cope with the average
25 flows in their watershed they return to complete the
26 cycle.

27 In summary we must try to
28 think water and remember that water flows. Being
29 landbased animals we sometimes get tricked. WE
30 try to put moving aquatic things on maps the way that

1 we map highways of forest that stay in one place.
2 Whenever we are in one place in an aquatic system we
3 should think about upstream, where our water habitat
4 is coming from and downstream where anything we do
5 will have its effects.

6 The origin of the Mackenzie
7 River system is usually thought of as Great Slave
8 Lake. Great Slave lake itself, however, has a water-
9 shed larger than that of the Mackenzie proper and
10 drains significant portions of Alberta, Saskatchewan
11 and British Columbia, as well as the Northwest Terri-
12 tories and the Yukon. The watershed in the Mac-
13 kenzie River system, including Great Slave Lake water-
14 shed, covers an area of approximately 700,000 square
15 miles.

16 For comparison, the whole
17 of the St. Lawrence River watershed including the
18 areas of the Great Lakes, covers an area of about
19 400,000 square miles. The distance from the head-
20 waters of the Mackenzie system on the Findlay
21 River to its outlets in the Beaufort Sea is more than
22 2,600 miles, although the Great Slave Lake to the
23 ocean section is perhaps 1,000 miles.

24 An important feature of the
25 Mackenzie system is the presence of three great lakes,
26 namely, Great Bear, Great Slave and Athabasca.
27 Great Bear and Great Slave have areas of about
28 twelve and eleven thousand square miles respectively
29 and are the third and fourth largest on
30 the continent, after lake Superior, Huron and Michigan.

1 At its downstream end about 100 miles from the sea,
2 the Mackenzie flows into its delta with hundreds of
3 shallow lakes and channels.

4 The Delta with its diversity
5 of shallow, fresh water and estuarine environments is
6 a particularly important feature of the Mackenzie
7 system as we shall see when we review its use by
8 fishes.

9 Two physical features of the
10 Mackenzie system require special mention as they
11 apply to aquatic systems. One is that the geology
12 of much of the watershed results in nutrient levels
13 being on the order of ten times higher than those
14 found in the Precambrian shield. These higher
15 nutrient levels are finally reflected in the higher
16 productivities of fish in the Mackenzie system by
17 comparison with the shield regions.

18 The second feature to note
19 is that the Mackenzie flows from south to north.
20 As a result, warmer water moves northward affecting
21 both the productivity of aquatic systems and parti-
22 cularly the distribution of fishes in the
23 system. It is quite likely that the relatively
24 large numbers of fish found in the Mackenzie is
25 at least partly due to the flow of warmwater from
26 south to north in the Mackenzie River system.

27 The Yukon River system in
28 total, the complete system now, has an area of
29 over 300,000 square miles, making the whole water
30 shed almost one-half the size of the Mackenzie

L.D. Doran
In Chief

1 drainage area. In Canada the Yukon River drains
2 large portions of the Yukon Territory. About 22,000
3 square miles of the Yukon watershed in Canada are
4 downstream of the area possibly affected by the pro-
5 posed pipeline.

6 The area includes the Porcu-
7 pine River and its major tributaries in the northern
8 Yukon Territory. The Porcupine joins the mainstem
9 Yukon in Alaska as it flows approximately westward
10 to empty into the Bering Sea.

11 An important physical dis-
12 tinction between the Yukon and the Mackenzie systems
13 is the lack of major lakes in the Yukon system.
14 There are no lakes that approach the size of Great
15 Bear, Great Slave or Athabasca lakes. It is impor-
16 however, to note that the Porcupine drainage in our
17 study area is a single watershed with all the
18 susceptibilities that that implies.

19 The north slope are both
20 at sea drainages in contrast are a series of relatively
21 small watersheds draining the north slopes of the
22 British, Barn and Richardson Mountains into the
23 Beaufort Sea. These are relatively small streams and
24 rivers by comparison with the Mackenzie and the
25 Yukon. Small lakes are also found in the watershed
26 although no large or great lakes are found. Streams
27 on the northslope have been classified into mountain
28 and tundra streams. Mountain streams are large, often
29 braided, have their origins in the mountains.
30 Springs are sometimes associated with these streams.

1 Tundra streams are beaded and
2 drain the tundra of the coastal plain and the slopes
3 of the foothills or the Arctic coastal plain. Lakes
4 and marshy areas that absorb water during heavy runoff
5 period may be associated with tundra streams as well.
6 Tundra lakes in the north slope watersheds are found
7 on the Arctic coastal plain. They are typically
8 shallow with abundant aquatic plants and no over
9 wintering fish.

10 Foothill lakes, by contrast
11 are deeper with stony bottoms and fewer aquatic plants
12 than tundra lakes.

13 In summary then it is import-
14 ant to recall that north slope watersheds are individual
15 separate systems without the accumulative effects of
16 a single system such as the Yukon or the Mackenzie.

17 To really appreciate the
18 water habitats of the north, we have only begun when
19 we think water. Next we must also think about winter
20 and frozen water, for not only does water flow but
21 it freezes, especially in the north. One of the
22 critical time periods in the life history of many
23 northern organisms including fishes, is winter.
24 Food supplies, water temperatures, and therefore
25 metabolic rates are low during winter. Productivity
26 is negligible because of the little sunlight
27 available for plant growth.

28 One strategy commonly
29 adopted by fishes is to find an area where they
30 can survive the winter without expending too much

1 energy. To carry out this strategy requires locating
2 water areas that do not freeze to the bottom in winter
3 and have water that contains enough oxygen to support
4 the fish through the winter. Other water quality
5 characteristics should also be within normal or accep-
6 tible ranges in order not to stress the fish during
7 the time of year when they are particularly vulnerable.
8 Obvious overwintering area is large bodies of
9 water such as lakes that do not freeze to the bottom.
10 The great lakes of the Mackenzie system are prime
11 examples, but the smaller lakes in the system can
12 be equally good over wintering areas if the waters
13 have enough oxygen and they do not freeze to the
14 bottom.

15 Most lakes of this size
16 will have species of fish such as lake trout, white
17 fishes, northern pike and smaller forage fishes that
18 are primarily resident in the lake. These fish spend
19 most of their lives in these larger lakes, although
20 localized movements into tributary streams to feed
21 during the open water seasons can be expected.
22 Lake fishes typically feed within the lake, however
23 on foods produced there.

24 The productivity of lakes
25 is based primarily on the plant foods produced
26 within the lake. These can be either rooted aquatic
27 plants that live on the bottom of the lake or
28 microscopic planktonic algae that float in the water
29 column. In either case, the growth of plants
30 results from plants themselves taking nutrients

L.D. Doran
In Chief

1 from the water in the presence of sunlight to
2 produce more plant material. Since sunlight is
3 required, there can be no growth of either rooted
4 or planktonic plants in lake waters that are deeper
5 than sunlight penetrates or in winter when there is
6 no sunlight. If the waters are very turbid and light
7 does not penetrate for that reason, this limitation
8 can be quite important in reducing total food produc-
9 tion in lakes.

10 The plant material produced
11 in these lake systems is eaten by small fishes or
12 invertebrates of various kinds which are in turn
13 consumed by larger fishes within the lakes. Since
14 the growing season is short and nutrients are not
15 abundant in sub-Arctic lakes, growth rates of fishes
16 are slow. In addition, the fish in these populations
17 are predominately large, old fish. Very often these
18 fish are 20 years old or more. The result seems to
19 be, according to one recent theory, that these
20 lake populations of fish are dominated by larger,
21 older fish which consume enough of some vital resource,
22 perhaps food or even space within the lake itself,
23 so that the younger, smaller members of the population
24 cannot grow even as fast as the productivity of this
25 system would otherwise allow. The predominance of the
26 older, larger fish, in effect, prevents the growth
27 of the younger and smaller members of the population.

28 Another result of this popu-
29 lation structure is that the whole population becomes
30 extremely vulnerable to the loss or removal of the

1 older fish. The larger and older fish would be quite
2 important for reproductive purposes if there were
3 a need to expand the population or sustain it through
4 a significant disruption.

5 If these large fish were
6 removed within some short time period, such as one
7 year, before the smaller members of the population
8 could reach reproductive size, the population
9 could be in serious trouble.

10 To summarize then, lake fishes
11 spend most of their lives in the lakes feeding on
12 foods produced there. The populations tend to be
13 dominated by large, old, slow growing individuals
14 that restrict the growth and numbers of smaller
15 fish in some way. These fish normally over winter
16 in the lake as well.

17 Another over wintering area
18 utilized by some species is the sea. Fishes that
19 live in the sea and return to spawn in fresh
20 water are called anadromous to distinguish them
21 from the resident species of fresh water. Anadromous
22 fishes typically undergo longer migrations than
23 the resident fishes which live in fairly localized
24 areas. Whether the anadromous fishes of the Mackenzie
25 system actually go well out to sea or remain in the
26 shallow and brackish areas of the Mackenzie Delta
27 is not known at the present time. Data are beginning
28 to accumulate however, to suggest that the inshore
29 Estuarine areas that we heard about from Dr. Livingston
30 of the Delta as well as the many channels and lakes

L.D. Doran
In Chief

1 in that area are extremely important areas for the
2 feeding of fish as well as for the over wintering
3 of these anadromous forms.

In Chief

Feeding by the young of these fishes in delta nursery areas seems to be of particular significance. Estuaries in general, particularly those with very turbid or silty waters tend to import much of their basic organic matter from outside the estuarine system. The turbid waters reduce light penetration to the point where phytoplankton -- phytoplankton are the microscopic floating plants in an aquatic system -- the phytoplankton themselves often can't grow in abundance. In addition the fluctuating environment, sometimes covered with salt water, sometimes covered by fresh water, is a difficult one for many species to adapt to. Although rooted plants can be abundant and extremely important in certain estuaries, much of the production that feeds estuarine systems often comes from somewhere else. The usual source of these organic materials is the river that flows into the estuary. Decayed or decaying plant material, dead or decaying invertebrates and vertebrates, organic matter of all kinds, fall into the river or its tributaries. As they are carried seaward these organic materials are physically broken down by the movements of the rivers' waters. In addition, bacteria begin to work on the dead organic matter and start breaking it down into its constituents. These particles of dead and decaying organic matter are generally referred to as detritus. When the detritus reaches the estuary it becomes food for the many organisms living there. In particular organisms living on or in the muddy bottom of the estuary are called benthos, literally eat up this

In Chief

1 detritus. One of the interesting academic questions
2 at the moment is, whether or perhaps to what extent,
3 this bottom living benthos feeds on the detritus
4 themselves, the detrital particles that come down from
5 upstream, or on the bacteria which are breaking down the
6 particles. But for our purposes here, the detritus
7 is known to be there and provides a major and significant
8 source of organic matter and therefore, energy, to fuel
9 the estuarine system.

10 The Mackenzie River, with it's
11 large watershed and more productive upstream, that is,
12 southern reaches, is likely a good source of detritus
13 for the Mackenzie delta region. The relative amounts
14 of energy contributed by these various energy sources
15 have not been measured to date. However the Mackenzie
16 delta is particularly interesting and valuable because
17 not only is it an estuary in the classical sense
18 we have just discussed, but also because as we have
19 heard the past couple of days, has a myriad of fresh-
20 water lakes and channels which are highly productive
21 environments in themselves. This diversity of productive
22 aquatic environment in itself provides a diversity of
23 habitats for fishes and fish foods.

24 So the anadromous fishes of the
25 delta have diverse and perhaps more abundant food supplies
26 by comparison with the lake and river habitats in the
27 system. Growth rates are still slow by comparison with
28 southern areas, but large numbers of relatively large
29 fish are produced. Fishes that are resident in
30 rivers and streams must be most careful in seeking out

In Chief

1 places to overwinter. Large rivers that flow all
2 winter or have deep pools with enough flow to sustain
3 fish through the winter, can be utilized for overwinter-
4 ing. These pools are risky areas however, since
5 conditions can be quite variable from one year to the
6 next. Pools that provide excellent winter habitat in
7 one year could well be cut off from their water supply
8 in colder years when flows between pools are reduced.

9 Small streams throughout
10 our study area tend to freeze to the bottom in winter.
11 These streams are not suitable overwintering habitat
12 for fish. There are some notable and significant
13 exceptions, namely streams that are supplied by springs.
14 These spring fed streams provide flowing water through
15 most winters, thereby sustaining fish life.

16 Overall and in general
17 however, fishes normally resident in small streams during
18 the summer must find other places to spend the winter.
19 Although they likely return to the smaller streams to
20 feed in summer, the streams are not suitable overwintering
21 habitat.

22 The fish food of small streams
23 and rivers are normally the aquatic forms of insects
24 that live on stream bottoms. These aquatic insects
25 feed on the detritus that falls into the stream as well
26 as on the algae which may be produced in the stream
27 itself. In addition, significant amounts of fish foods
28 can be derived from terrestrial insects or other forms
29 that fall into the stream.

30 Growth of fishes that are stream
and river resident are normally slow, perhaps slower

In Chief

In all these habitat types in all the watersheds we are considering, there can be significant differences in conditions between years. And particularly between winters, when fish overwintering areas are critical to the survival of the populations. In terms of impact of these overwintering populations then, the kind of winter and the specific areas to be

In Chief

1 affected could be critical.

2 Now, I would like to turn
3 briefly to the question of how these northern aquatic
4 systems compare with those in other regions. The
5 general topic may also provide us with some insight into
6 the uniqueness of these northern systems, and the areas
7 about which we still have very little understanding.

8 As a kind of preface to this discussion, I would like
9 to mention one of the few laws or rules, if you like, of
10 biology. Perhaps it should be called an axiom, and
11 perhaps with the previous discussion we have heard it is
12 so obviouse as to need little emphasis. However, it is
13 important to remember as we discuss the fragility and
14 the stability, resilience of northern systems. And the
15 rule is that organisms are adapted to their environment.

16 The process of evolution with its complicated workings,
17 some of which are still little understood, results in the
18 animals and plants of an area being adapted to the
19 environment in which they live. This much is known and
20 is almost self evident. If an animal lives and reproduces
21 successfully in an area anywhere, it has adjusted it's
22 life cycle to that of the surrounding environment. It
23 is adapted.

24 Now, since most of the physical
25 environment of the surface of this planet have biological
26 communities associated with them. We see that these
27 environments are sutiable for life as it has evolved
28 here. Or perhaps we mean that life has been able to
29 evolve here to its present complexity because the
30 environment, is what it is.

In Chief

1 Either way, the process is
2 complementary, and the organisms, living and reproducing
3 and reproduction is important, continued reproduction in
4 an area, are adapted to that area. So when people talk
5 about stressfull environments or harsh climates, they
6 usually do not mean that nothing can live there. Almost
7 all the environments commonly encountered do support
8 life. What people do mean when they mention environments
9 that are harsh, or exert stress on animals and plants
10 is that there are only a few species or organisms that
11 can live there. If an environment that is rather
12 benign and fairly constant, such as a tropical environment,
13 can support hundreds of species of fish, or even thousands
14 of species of fish, then an comparable arctic or even
15 temperate enviroment will only support tens of species
16 of fish.

17 The analogy applies directly
18 as we've heard already today to northern aquatic systems.
19 There is low species diversity in the arctic which means
20 there is few species of a given kind of animal or plant
21 present. The reasons for this simple structure in
22 northern systems are subjects of many published papers
23 and long discussions between experts. However the
24 explanation that I like best, is that the large fluctuations
25 that occur in high latitude environment require that the
26 individual species which live there have a very wide
27 tolerance to environmental change. In tropical environments,
28 where changes in wheather are very small, the species
29 there can afford to become adapted to a very small part
30 of the environment. In arctic areas, where the weather

In Chief

1 changes in major ways, the species that survive there
2 must be able to deal with these wide ranges of weather
3 conditions, and really cannot afford to become too
4 specialized.

5 So the structure of arctic
6 systems is simple. There are few species found, but
7 these species are individually very adaptable in order
8 to survive in the wide range of climatic conditions
9 they must face. A second major consideration in under-
10 standing arctic systems is their low productivity.

11 The total energy input into these areas is perhaps one
12 half what it is in more southern areas. The long dark
13 winter means that no plants can grow during that time.
14 The cold temperatures over much of the year mean that
15 most biological processes work very slowly. Fish grow
16 slowly as well. As we have seen, big fish in the north
17 result from many years of very slow growth. This slide
18 illustrates how substantial the differences can be in
19 terms of the amounts of fish produced by lakes though
20 out the world.

21 This scale is an indication of
22 the productivity of these lakes. The bottom line
23 represents a polar lake, the top line represents a
24 tropical lake, and the scale is logarithmic. So that
25 if this is the productivity of one in some arbitrary
26 unit, and it is, one here, the one is just between the
27 polar and the sub-arctic lake, the productivity of the
28 similar in the arctic, in the tropical regions, a lake
29 with similar shape, is about one hundred. The other
30 lines demonstrate temperate lakes, sub-tropical, tropical

In Chief

1 lakes in between.

2 THE COMMISSIONER: Mr. Doran,
3 so that I understand the terminology, where would you
4 classify say, Anderson Lake, where Great Bear, and where
5 Great Slave?

6 A Right, this is a global
7 comparison of lakes, so that the lakes that we are
8 considering would be in this region of the graph, polar
9 and primarily sub-arctic--

10 Q Do you use "polar" as a
11 synonym for "arctic"?

12 A Yes.

13 Q Oh, I see.

14 A It could be used in this
15 case, sure, so that we are in this region of the graph
16 around 1, the productivity in the region of one, and
17 a tropical lake on this kind of scale would be up about
18 around one hundred. The productivities are quite
19 different between these regions.

20 Q Lake Athabasca would come
21 where on that chart?

22 A It would be in the same,
23 a little higher perhaps, between the sub-arctic and the
24 north temperate. We would start moving towards our
25 temperate lakes.

26

27

28

29

30

L.D. Doran
In Chief

1 The Great Lakes of Southern
2 Canada, for example, might be down in this more temper-
3 ate region.

4 THE COMMISSIONER: Thank you.

5 A The critical question
6 then, in terms of these systems, is how these simple
7 slow-growing Arctic aquatic systems respond to stress.
8 This slide is intended to give us some ideas about
9 this. The slide shows how the structure of tropical,
10 temperate and Arctic coastal systems respond to stress.
11 Again it's a very generalized diagram. This axis is
12 the increasing amounts of stress applied to the system.
13 This axis is the amount of structure or the diversity
14 of the system. So as we move along, this axis is
15 increasing the stress on the system; this is a system
16 of increased structure.

17 These are tropical systems,
18 these are temperate systems, these are Arctic systems.
19 The green fills are undisturbed and the red fill are
20 disturbed systems. In this generalized diagram, with
21 disturbance, a tropical system would move from this
22 structure fairly high, very diverse, to one of a lower
23 structure. The temperate system would move from one
24 of more moderate diversity to less. The Arctic system
25 would change slightly with increased stress.

26 Q Could you give me one
27 or two as examples of that?

28 A The stresses would vary
29 depending on the kind of system. Dr. Livingston gave
30 an example of coral reefs. Disruption would be an

L.D. Doran
In Chief

1 increase in temperature, that would be a stress on
2 the system. A quite common stress in a tropical
3 system like that is large inputs of fresh water from
4 some source. Temperate systems, temperate aquatic
5 systems, introduction of a new species, of a new
6 parasite would prey on some form, a very heavy fishery
7 on the resource; and things we can't predict in advance,
8 any kind of major disruption to the system as a whole.

9 Now looking at this slide we
10 can see in each case there is a reduction in the number
11 or diversity of species under stress, in all three
12 systems. The system becomes simpler, and complexity
13 is lost. An important point to note is that the
14 stress systems are very similar in structure in all
15 three environments, so tropical, temperate, and Arctic
16 systems in this example are low in diversity under
17 stress. Stressing a tropical system results in a
18 simplification of that system to the point where its
19 structure is very similar to a disturbed temperate
20 system. Both of these become analagous to the
21 simple Arctic systems we have been discussing here.

22 We should also notice, however,
23 that relatively little change takes place in the
24 Arctic system under stress. One reason is that the
25 natural stresses are high already. Temperatures are
26 cold, productivity is low, and fluctuating environments
27 are commonplace. So in one sense the Arctic systems
28 are ready for disturbance. They live with it all the
29 time. The structure of these Arctic systems is
30 nearly as simple as it can get, and additional stress

at intermediate levels has little noticeable effect.

For flowing systems in the north, such as rivers, streams and estuaries, the likelihood of stressing these systems to the point where they change qualitatively, seems low. However, this is one of the major gaps in our understanding. We have very limited experience with stressing these Arctic systems. We don't know in detail what amounts of disturbance can be tolerated without changing the system completely. Since we know so little about these things, biologists' judgments should be and usually are very conservative. We recommend that disturbance be kept to a minimum in the hopes that it won't be too great.

Parathetically we might note

L.D. Doran
In Chief

1 that since we know so little about the system effects
2 of disturbances, that when they do occur we should
3 be learning from them. As changes are imposed by
4 man and their effects studied, understanding can be
5 expected to advance to the point where we know better
6 how to manage each system.

7 In summary then, we should
8 note that Arctic systems live under considerable
9 natural stress, mostly related to the major climatic
10 changes that occur every year. Additional stress up
11 to moderate levels seems to have little effect on
12 these systems, but major disturbances may destroy them
13 completely, at least locally.

14 We might also note, however,
15 that these characteristics are not unique to northern
16 systems. There can be highly stressed environments
17 in any of the climatic regions of the world. Tropical
18 beach subjected to the pounding of the surf is a highly
19 stressed environment to the little bugs that live between
20 the sand grains. From their point of view, living on
21 a tropical beach is not too different from an exposed
22 beach on the west coast of Canada or Alaska.

23 The uniqueness of northern
24 aquatic systems and the Mackenzie system in particular,
25 is that it exists. The Mackenzie is a major river system
26 flowing from south to north. It contains three great
27 lakes and a large and impressive delta. This range and
28 diversity of aquatic environment is likely not matched
29 by any other single system in the world. Soviet Union
30 has several river systems comparable in size, that flow

L.D. Doran
In Chief

1 from south to north. However, none have anything
2 similar to the great lakes of the Mackenzie system.
3 So the system, as a system, as an aquatic system, is
4 quite likely unique.

5 Another characteristic of the
6 Mackenzie which, though not unique, is extremely
7 important, is that it is not significantly polluted.
8 In a world where increasingly scientists and serious
9 students of nature assume pollution until proven
10 otherwise, the Mackenzie River system is an important
11 resource. Scientific, educational and cultural values,
12 partly because it is not polluted, are tremendous, and
13 this is without considering the survival value of
14 this system to people who rely upon it for food, a
15 point which Chris Hatfield will consider in some
16 detail.

17 In summary then, northern
18 aquatic systems are simple in structure and adapted
19 to stress. They are likely to react to large scale
20 additional stress by local extinctions. Though these
21 conditions are not unique to the north, the Mackenzie
22 system as a whole is probably a unique aquatic system
23 in the world. Its component parts are duplicated in
24 other areas but as a whole it is a unique aquatic
25 system. The fact that it is not significantly polluted
26 at present increases its value for future generations.

27 Now Chris will explain how
28 these system characteristics relate to the fishes of
29 the area.

30 THE COMMISSIONER: Thank you

L.D. Doran
In Chief
C.T. Hatfield
In Chief

1 very much, Mr. Doran. I am very grateful to you for
2 that lucid and extremely careful explanation of the
3 subject. We will hear then from Mr. Hatfield, will
4 we, Mr. Scott?

5 MR. SCOTT: Yes, certainly.

6 THE REPORTER: Are we expected
7 to sit from 9 A.M. to about 6 P.M. every day?

8 THE COMMISSIONER:
9 I expect, gentle-
10 men, that we will sit from 9 A.M. to about 6 P.M.
11 every day but in order to remain on schedule in this
12 overview hearing so that we can begin phase 1, that is
13 the engineering and construction evidence on Tuesday at
14 9 A.M., I thought it best that we hear this evidence,
15 all of it today. That may be an injustice to Mr.
16 Doran and Mr. Hatfield, but I think that speaking for
17 myself I have found it just as -- I won't say easy to
18 absorb but I've been just as capable of absorbing it
19 as I was absorbing what we heard earlier today, so
20 carry on.

21
22 CHRIS T. HATFIELD, sworn:

23 THE SECRETARY: Will you
24 give your full name, please?

25 / A Chris T. Hatfield.

26 DIRECT EXAMINATION BY MR. SCOTT:

27 Q Mr. Hatfield, I understand
28 that you're a B. Sc. in fishery zoology at the Univer-
29 sity of B.C.

30 A That's correct.

Q And an M. Sc. in aquatic

C.T. Hatfield
In Chief

1 pollution ecology from Queens, Kingston.

2 A Yes.

3 Q And that from 1972 to
4 1975 you were the senior manager of an environmental
5 impact assessment program for the Environmental Protec-
6 tion Service of Environment Canada.

7 A Yes.

8 Q Would you tell us briefly
9 what you did there?

10 A It was a combination of
11 programs dealing with ecological impact problems on the
12 Pacific Coast and also oil spill problems.

13 Q And can you tell us some
14 of the particular projects in which your -- you worked
15 under that program?

16 A We had a number of
17 developments that were going on on the Pacific Coast,
18 they're still going on, and the Vancouver Airport
19 expansion program, different harbour developments up
20 and down the coast, railway developments in northwestern
21 B.C., etc., etc.

22 Q Well now, apart from
23 that work, have you had -- have you been engaged in
24 the private sector of the economy?

25 A I spent one field season
26 with F.S. Sweeney and Company, and recently have
27 gone out on my own as a private consultant.

28 Q Would you like to carry
29 on, Mr. Hatfield, as your colleague did?

30 A I might say just to add

C.T. Hatfield
In Chief

1 one bit of explanation, my time with Environm ent
2 Canada previously to E.C.S. time was spent in Winnipeg
3 supervising Arctic research on fish. That's the reason
4 I'm here.

5 Q How long was that?

6 A That was about three
7 years, I spent three summer field seasons in the
8 Arctic.

9 THE COMMISSIONER: Well, don't
10 hesitate to bring out anything else that Mr. Scott
11 has overlooked.

12 (LAUGHTER)

13 MR. SCOTT: I would just say
14 that Mr. Hatfield has helpfully filed a brochure which
15 will be available, that lists his various publications
16 and his other academic and practical experience. I'll
17 see to it that the Commissioner reads it.

18 A Thanks very much.

19 Mr. Commissioner, ladies and
20 gentlemen, Lee Doran has given you an overview of
21 aquatic ecological systems, how they work, unique
22 characteristics they have in the north, and how they
23 present different habitats for fish communities.

24 In the next 40 or 45 minutes
25 I will be covering the fish resources in the areas
26 where the pipeline may go. That's the last four
27 points in our summary.

28 I will start with a description
29 of the current state of our knowledge of northern fish
30 resources, cover the general characteristics of

C.T. Hatfield
In Chief

1 northern fishes and fish populations, and then present
2 some detail on what we know of fishes in the Mackenzie,
3 Yukon, Porcupine and Yukon north slope drainages.

4 Human utilization of fish
5 resource in the past, present use and future potential
6 use, will be covered in terms of the domestic, commer-
7 cial and sports fisheries.

1 I will discuss factors vital
2 to the fishes survival and health of the stocks,
3 and the resilience of northern fish species to
4 environmental disruption. The conclusion of the
5 talk will include a summary of the main points to
6 remember about northern ecological systems.

7 What then is the state of our
8 knowledge of northern fish? Arctic aquatic ecology
9 has attracted the interest of academic research
10 people for the last 30 or 40 years. Operating on
11 very limited budgets, scientists such as McPhail,
12 Lindsay, Johnson and Hunter sketch a general picture
13 of the fish population and fisherie potential up
14 until 1970. In the last four years a major effort
15 supported by the petroleum industry and federal
16 government was mounted to refine previous knowledge,
17 fill many gaps which existed in our understanding of
18 northern fish and most important, get results into
19 public reports where they could be used in the
20 decision making process on the pros and cons of
21 northern development.

22
23 The studies concentrated
24 along the Mackenzie, Porcupine and Yukon north slope
25 watersheds. A vast amount of data was gathered
26 and analysed. Many questions and standing stocks,
27 migration routes, spawning areas and the timing of
28 these events were answered. Significant gaps and
29 refinement
30 lack/of data remain however.

Some of the important gaps

1 are the failure to positively identify spawning,
2 overwintering, nursery and feeding areas of many
3 fish species. Life history details are missing
4 such as the activities of anadromous fish in the
5 marine phase of their life, we do not know what happens
6 to them when they go to sea. The movements and
7 feeding of fish in winter, and the behavioural patterns
8 of species during each segment of their life
9 cycle.

10 The importance of watershed
11 and delta lakes to fish species is not understood
12 although the presence and absence of fish in many
13 of the lakes at different times of the year suggests
14 they are utilized for specific purposes by fish popu-
15 lations.

16 One of the most outstanding
17 gaps in our knowledge of northern fish is the lack
18 of information on their susceptibility to natural
19 and manmade environmental change. What are the
20 effects of an unusually cold or long winter on
21 over wintering areas? What happens to spawning
22 grounds when unusual freshets or construction activi-
23 ties upstream cause an increase in siltation in
24 the stream? What are the tolerances of northern
25 fish to chemical pollution? Stream temperature varia-
26 tions? Changed stream velocities?

27 Few studies have been done
28 on these subjects for northern fishes. Most of our
29 advice from biologists on possible effects on
30 northern fish have been environmental changes, is

In other species, such as

Because of the low productivity of northern waters, Arctic fish are usually opportunistic feeders. Terrestrial insects bottom fauna, other fish, and quite often almost any organic matter which an individual comes across will be ingested. Certain species such as grayling specialize in terrestrial insects while others such

1 as Longnose Suckers feed mainly on bottom detritus
2 when a choice is available. Most northern fishes
3 have specific migration routes and limited spawning,
4 over wintering, nursery and feeding areas.

5 I will comment on the life
6 cycles of the various species and relate them to
7 geographic areas later.

8 What then are the major differ-
9 ences in the fish resources among the three geographic
10 areas over which the pipeline may go? The Mackenzie
11 River, because it originates in warmer latitudes,
12 where the climate is less severe than the Arctic, is
13 more productive and therefore has more fish species
14 than either the Porcupine or north slope drainages.
15 34 Species have been found in the Mackenzie, 16 species
16 in the Porcupine, and 7 in the Yukon north slope rivers.
17 I might say that these numbers are very small. The
18 Amazon River by comparison has something like 2,500
19 species. They are still finding more.

20 Significant runs of Pacific
21 Salmon in the Porcupine-Yukon drainage and Arctic
22 Char in the north slope and the Mackenzie Delta
23 rivers, single them out as being especially important
24 however, with our present high values put on the
25 salmon and char species. Few salmon or Arctic Char are
26 found in the Mackenzie River drainage south of the
27 Delta, although some individual pink and chum salmon
28 do make the thousand mile journey from the Arctic
29 Ocean to Great Slave Lake to spawn. They swim all
30 the way up that long river.

C.T. Hatfield
In Chief

Ground water springs

provide important over wintering and spawning areas on northslope rivers. Porcupine, Arctic Red, Peel, Liard, Great Bear and the Mackenzie mainstems appear to provide spawning and over wintering capabilities in the other two areas.

As one would expect species similar common to all three areas have life histories in each area. But migration patterns, over wintering, spawning, nursery and feeding areas are specific to each location. What are the significant facts in the life cycles of the major species in each geographic area? For ease of presentation, I will lump the different species into spring spawners and fall spawners. Obviously I cannot go through 34 species in detail. The significance in this division is that the eggs of the fall spawners have to survive the rigors of the winter environment and lay in the gravel from October until break up the following spring in May or June when the fry hatch and move to the nursery areas.

Spring spawners deposit their eggs at break up and the young emerge within a few weeks. There is, therefore, a large difference in the lengths of time that the eggs are vulnerable to environmental disruption between the two groups.

First we will discuss the Mackenzie River fish species. In this watershed the fall spawners constitute 62% of the species and spring spawners about 35%. The Burbot, a fresh

1 water cod is a winter spawner in the system. Major
2 spring spawning species are Arctic Grayling, a fish
3 distinguished by its dorsal fin, large dorsal fin,
4 large yellow Walleye, northern pike, longnose
5 sucker and flathead chub . The Arctic Grayling is
6 distributed throughout the system and is probably
7 a most important species of the spring spawners.
8 Grayling under go a complex seasonal migration,
9 spawning usually takes place over gravel, in small
10 relatively clear tributaries during spring break
11 up. The mature fish then appear to migrate to other
12 feeding areas in the Mackenzie system, overwintering
13 in lakes or the mainstem channels. IN one
14 population the post spawning adults from the three
15 day lake system in the Norman Wells area, move down
16 stream to the Mackenzie River, then upstream again
17 to become resident in the Great Bear River
18 over summer.

19 Nursery areas for fry and imma-
20 ture fish are generally in the clear, swiftly flowing
21 smaller tributaries. Summer food of this species in
22 the Mackenzie is mainly terrestrial and aquatic
23 insects.

24 Two other spring spawners,
25 pike and walleye are abundant in the southern Macken-
26 zie. Walleye decline in numbers further north.
27 These two species spawn in tributaries in the system
28 moving short distances to deep, darker, mainstem
29 rivers and lakes in summer where presumably they
30 overwinter. Pike are usually found in the shallow

C.T. Hatfield
In Chief

1 back eddies and weedy areas of the Mackenzie system.
2 Both species feed mainly on smaller fish in the
3 aquatic community. Longnose sucker and chub are
4 spring spawners adapted to turbid waters. Some
5 chub migrations do take place in the system. These
6 two species are mainly bottom feeders.

7 FALL spawners in the Macken-
8 zie are dominated by their Coregonid or whitefish
9 class. This is a list of the species that are gener-
10 ally in that class. The hump back, broad and round
11 whitefish, Artic and least cisco and the Inconnu.
12 With the exception of the larger lakes, these species
13 have larger populations in the north end of the Macken-
14 zie drainage. Large populations of humpback white
15 fish and to a lesser extent, cisco and inconnu also
16 occur in Great Slave and Great Bear lakes and the
17 surrounding rivers and smaller water bodies. It
18 is a hump back whitefish.

19 Well defined spawning migrations of the
20 white fish family take place in the Mackenzie
21 Delta channels. The Arctic Red, Peel, Great Bear,
22 and the Mountain Rivers. Arctic and least Cisco
23 spend much of their life cycle in the sea. All these
24 species extensively use the Delta channels and
25 brackish Mackenzie estuaries for feeding, nursery
26 and overwintering areas.

C.T. Hatfield
In Chief

eco
This area where two systems
meet, the sea and the fresh water. The coregonid
species begin migrating through the delta in August,
and spawn in the upper delta, Arctic Red, Peel, and
Mackenzie main stem rivers in September and early
October. Post-spawning runs occur back down these rivers
in late October and November. This graph shows how
the spawning migrations are measured. This is a samp-
ling station we had at Arctic Red River and a
measured length of gill net would be put in the river
and fish caught in the net every two weeks, I think.
This was for the year 1971, there's a date along the
bottom and the numbers of fish along the vertical
axis, for each species, so you can get an idea on this
graph just when the runs were going by Arctic Red
River.

The right and the left border
of the graph are unfortunately cut off by spring
breakup and fall freezeup, at which time it's a little
difficult to set a gill net.

The coregonid species appear
to spawn under a variety of bottom sub- strata and water
turbidity conditions. The fry are carried downstream
to the Mackenzie Delta and estuary by the spring floods
the next year. Arctic and least cisco and inconnu
stop feeding during their spawning migrations. They
live on stored body energy until returning downstream.
I'll return to that point later, it's quite an important
point.

Humoback and broad white fish

C.T. Hatfield
In Chief

are generally bottom feeders with insect larvae and small shelled organisms making up the largest portion of their diet. Small fish form a large part of the inconnu diet. Cisco species are plankton feeders. Lake trout occur in significant numbers in the deep lakes of the Mackenzie tributaries and the delta. Great Bear and Great Slave Lakes have large populations. They do not appear to be a major species in the flowing waters of the system, however.

Arctic char, another important fall spawner in the northern Mackenzie system, spawns and over-winters in the Peel and Big Fish Rivers. I will describe the species a little more fully when I start my discussion on north slope fishes.

Burbot are the only winter spawners in the system, the spawning taking place in February and March over sand and gravel. In other words they're out there now underneath the ice doing their thing, I guess.

This species occurs throughout the Mackenzie drainage, mainly in the deeper lakes and river channels. It is a voracious feeder of smaller fish and appears to follow species such as Arctic greyling on its ^{life} cycle migrations in the system.

Other species occurring in the Mackenzie system include two species of dace, shiner, stickleback, sculpin, and smelt and a few goldeye. Each species, of course, has its own life history and no doubt contributes its part to the aquatic community. These are minor species by number,

C.T. Hatfield
In Chief

1 however.

2 The second geographic area I
3 will describe from a fish resource point of view, is
4 the Porcupine River drainage, a major tributary to the
5 Yukon. New elements here are the substantial runs of
6 salmon migrating up the Porcupine in the fall and the
7 absence of Arctic char in the system.

8 As in the Mackenzie, spring
9 spawners and dominated by the Arctic greyling which are
10 found throughout the system. Life habitats are
11 characteristic of the species with each population hav-
12 ing its spawning cycle in specific small streams.
13 Then moving to the large rivers and lakes for summer
14 feeding and perhaps moving again to a different
15 location for over-wintering. Northern pike and long-
16 nosed suckers are found in the larger waterways of
17 the system. Yellow walleye are not.

18 Three species of salmon domin-
19 ate catches in the main stem rivers in fall heading
20 for spawning grounds mainly centered on the springs
21 area of the /Fishing Branch River. They, of course start
22 their journey at the mouth of the Yukon River in
23 Alaska, chinooks beginning their arrival at Old Crow
24 in late July, chum in early August, and coho in early
25 November. The salmon run peaks in October. Chum
26 salmon numbers are estimated between 115,000 and 250,000
27 depending on the year. Lesser numbers of chinook and
28 coho salmon have been recorded. The salmon species
29 have differing life cycles, but the progeny of coho
30 and chinook remain to feed in fresh water for two to

C.T. Hatfield
In Chief

1 three years before migrating to the sea, and the chum
2 salmon fry going directly to sea after hatching the
3 following spring. All adult Pacific salmon, of course,
4 die after spawning.

5 Fall spawners of the coregonid
6 class, as in the Porcupine, as in the Mackenzie, include
7 the inconnu, least cisco, humpback, broad and round
8 white fish. The missing species is the Arctic cisco,
9 which of course is found in large numbers in the
10 Mackenzie. Little is known about the runs and spawning
11 areas of these fish, as no readily identifiable migra-
12 tion patterns have been found in studies. It seems
13 reasonable to assume that these species migrate upstream
14 in late summer and early fall to main stem spawning
15 areas at the mouths of the larger tributaries of the
16 system, and then return downstream to over-wintering
17 areas in the deeper lakes and channels in late September
18 and October. Food for these species is probably similar
19 to that found for Mackenzie system white fish.

20 Burbot, the winter spawners,
21 are found in a few of the main stems of the Porcupine
22 drainage. Trout, perch and chub are found in the
23 Porcupine drainage, are important forage fish for the
24 piscivorous species such as pike, inconnu and burbot.
25 "Piscivorous" means fish eating by the way.

26 The third area of our fish
27 resource discussion is made up of the north slope
28 drainage. Fish in these areas have a lower growth
29 rate than the same species in the Porcupine and the
30 Mackenzie. They mature later, and the whole resource

C.T. Hatfield
In Chief

1 is less productive than that found in the other two
2 systems. Probably the most important habitat of
3 north slope drainages are the spring areas used by
4 char and greyling in particular for spawning and
5 over-wintering. Of the spring spawners, the Arctic
6 greyling is again a major species in almost all the
7 systems. Individuals are smaller than the Porcupine
8 and the Mackenzie drainages and have slower growth
9 rates. Their life cycle is centred around the springs
10 and deep pools of the relatively small north slope
11 rivers. In winter the shallowriffle areas of these
12 streams freeze to the bottom, leaving no room for
13 the fish to live. The springs and pools therefore
14 become critical for spawning, over-wintering, nursery
15 areas, and feeding to the greyling. Most of these
16 areas are identified by having large expanses of
17 off-ice in summer, and are open water in winter.
18 That's a rather poor picture of off-ice, but essentially
19 it is just large expanses of ice caused by the springs
20 which flow all winter long, and of course the ice
21 takes longer to melt in the summer.

22 Many have been mapped and
23 described in the north slope drainages. The only other
24 spring spawner found in a few of the north slope rivers
25 is the northern pike. The most important fall spawner
26 in this area is the Arctic char. As with the
27 greyling, spring and pool areas in the north slope
28 system are critical for the survival of this species.
29 Arctic char spawn in late summer and fall, in the
30 vicinity of the spring water sources; and fry emerge

C.T. Hatfield
In Chief

1 the following year in April and May to spend their
2 first year feeding in the streams. Then they return
3 to the spring and pool areas for over-wintering. This
4 process may go on for several more summers until the
5 physiological change takes place in the young juveniles
6 which results in a spring downstream migration to the
7 Beaufort Sea as smolts. The char then spend the
8 summer in the sea but return to the north slope drainages
9 in late fall to over-winter. Presumably the cold marine
10 waters would freeze their body fluid if they stayed at
11 sea, though this isn't known, this is an assumption.
12 The growing young char make the fresh water sea journey
13 two or three times before they finally mature and
14 spawn again in the spring areas. Like Atlantic
15 salmon, the char often go through the spawning cycle
16 several times before dying. Young char feed on
17 insect larvae and fresh water shrimp. As they increase
18 in size, snails and other fish become increasingly
19 important in their diet. Several species of coregonids
20 are found in this area, including the humpback, broad
21 and round white fish, and least cisco. The spring
22 areas are also very important for these populations.
23 A species of sculpin and stickleback are also found
24 in north slope systems.

25 O.K., how does man utilize
26 the fish resource in the Western Canadian Arctic?
27 There are three kinds of fish resource utilization in
28 the north. The domestic, commercial and sports
29 fisheries. These three purposes for fishing overlap
30 in some areas with each fishery competing for the same

C.T. Hatfield
In Chief

1 species. This overlap will probably increase in
2 future and have to be carefully managed. The domestic
3 fishery has traditionally been very important throughout
4 the area as a source of protein. R.C.M.P. stations,
5 church missions, Hudson Bay posts, and the native
6 inhabitants of northern settlements depend on fish
7 for part of their diet and their dog transportation.
8 The domestic fishery has declined somewhat since the
9 snowmobile has replaced dogs in many areas. However,
10 the catch is still very important to northern people.
11 Fishing is done mainly with gill nets around settle-
12 ments, and fishing camps at breakup, freezeup, and
13 under the ice in January and February. The catch
14 is usually dried, smoked, frozen, or stored in perma-
15 frost pits for later use by dogs. Fish subsidizes
16 many other sources of food in the north, particularly
17 in settlements such as Old Crow and the delta communi-
18 ties. If the other sources of food such as caribou
19 and migratory birds are not plentiful, more fish are
20 caught and used as a diet replacement.

21 Actual^{catch}/statistics in the
22 domestic fisheries are very poor and vary from
23 settlement to settlement, and year to year.
24 However, the following are typical. In 1961-62,
25 about 350,000 pounds of fish were caught at Fort Good
26 Hope. In 1972, about 100,000 pounds. 113,000 pounds
27 were caught in Aklavik in '61-62; 2,160,000 pounds in
28 1966, and about 295,000 pounds in 1973. Of the
29 295,000 pounds caught in Aklavik in '73, most of the
30 humpback white fish, broad white fish, and Arctic cisco

C.T. Hatfield
In C hief

1 comprising about 80% of the catch, were utilized as
2 dog food. The remaining inconnu, Arctic char,
3 burbot and some broad white fish were consumed by
4 people in the settlement.

5 People in Old Crow on the
6 Porcupine system caught about 10,000 salmon in 1971,
7 and 3,000 fresh water fish. A summer camp of
8 Eskimos on Herschel Island caught about 300 char and
9 300 cisco for their own use in 1971. I mention
10 this because many of the camps that are out from the
11 settlements, of course the inhabitants of the camps
12 do a lot of fishing for their livelihood while they're
13 out there.

14 There is little other domestic
15 fishery utilization of north slope fish resources.
16 Federal Government policies for the future in the
17 Arctic is to ensure that native people in the north
18 have the option of retaining their traditional way of
19 life. In line with this, the 1972 Federal Territorial
20 Task Force looking into fisheries development in the
21 north recommended that harvesting of fish for domestic
22 purposes should take precedence over commercial or
23 sports fishery development.

24 Only 4% of the economic returns
25 to the total Canadian commercial fishery comes from the
26 lakes and rivers of the Northwest Territories, which
27 constitute about 60% of the fresh water area in Canada.
28
29
30

C.T. Hatfield
In Chief

The reasons for this disappointing harvest are slow growth rate in northern fish, being too low production in the stock and extremely high transportation costs in moving the fish to markets in the south. Commercial fishing started in earnest on Great Slave Lake in about 1945. The white fish family are the most important species harvested. The Great Slave Fishery, and contributions from lakes surrounding it, still contribute the largest percentage of the 5,000,000 pounds caught annually in the Northwest Territories. Normal fish stock management economics are uneconomical in the north except in the very large lakes, because of the low annual production available for harvesting. Many of the smaller lakes where commercial fishing is established are fished on a six-year cycle, six years of estimated annual harvest is taken from the lakes in two years, after which the lakes lie fallow for four years and then are ready to be fished again.

Approximate potential of annual yield for fresh water areas in the Northwest Territories is estimated to be about 15 million pounds. Commercial fisheries could then grow about three times its present size of about 5 million pounds annual in the Territories. Marine and estuary areas off the Mackenzie River also give promise of some commercial fishery potential. The Northern Yukon, which has no commercial fishery at present, could presumably add some to the total commercial fishery yield in the north. One of the most promising areas for future

C.T. Hatfield
In Chief

1 commercial harvest is in the Mackenzie Delta. A small
2 experimental commercial fishery on the east delta channel
3 of the Mackenzie in 1973 readily caught its quota of
4 3,000 pounds of inconnu and 50,000 pounds of broad
5 white fish. Hopefully this will develop into a good
6 local fishery for northerners.

7 Sports fishery represents the
8 greatest potential for northern fish resource development
9 with far greater economic returns per fish harvested
10 with less strain on the resource than the commercial
11 fishery. To benefit northerners significantly, the
12 management system which leaves most of the economic
13 returns in the north will have to be developed. In
14 the past fly and sports fishing camps for lake trout
15 on the east arm of Great Slave Lake and around Great
16 Bear Lake have done well, but are owned by Americans
17 and Southern Canadians, with the returns going south
18 at the end of each season.

19 Arctic greyling stock through-
20 out the Mackenzie drainage /and Northern Yukon have
21 great potential for sports fishing, as do char and
22 lake trout in the north slope of the Mackenzie Delta
23 waterways. With more road access and increasing
24 settlement in the north, diversion and tourism potential
25 provided by good sport fishing will become increasingly
26 valuable. I don't think I'll tell anybody where that
27 fish came from.

28 What then are the factors
29 vital for fish and fisheries survival in the north?
30 Spawning grounds, migration routes, water environment

chemistry and food sources are some of the critical factors for survival in a fish's life history. The importance of these things is probably more emphasized in the north because of the generally decreased resilience of fish populations to bounce back to natural levels after a severe environmental disruption has reduced their numbers.

Most northern fish species require spawning grounds free of silt, having the correct substrate, usually clean gravel, and suitable water temperatures. Here you can see a fish egg sitting in gravel and you can see the water area around the egg. The gravel must be free of silt to allow water to percolate around the deposited fish eggs and to permit gas exchange across the egg membranes with the surrounding water. Silt from a natural or man-made source can originate from an area many miles from the spawning ground itself. This is the water flow concept that Lee was talking about. Obviously if spawning gravel is removed from a stream for construction purposes, this important habitat would be lost to the species. Potential disruption on spawning grounds would be particularly serious in the Arctic because of the severely restricted areas near springs and deep pools where spawning can successfully take place, without the eggs freezing over the winter.

Spawning migration routes and times are very important for many northern fish species. Blocked or sufficiently disturbed river beds which prevent fish from returning to normal spawning

C.T. Hatfield
In Chief

1 areas of course affect spawning success. This is a
2 winter road which is built across a stream during the
3 winter and if that's not cleared out, it stays as a
4 block in the summertime.

5 Some species do not feed en
6 route to spawning areas, and therefore any significant
7 delay in their migrating time could leave them with
8 not enough body energy to leave these areas, to move
9 to these areas. There is some evidence that many fish
10 species populations are divided into races, each with
11 its own migrating pattern, time, etc. Species with
12 this sort of makeup are more vulnerable to environmental
13 hazards because of the slow repopulating ability of
14 habitat areas left vacant when specific races are
15 reduced in numbers. The salmon would be an example of
16 that sort of species.

17 Changes in water/turbidity, temperature
18 or chemistry can also affect fish populations. Unusual
19 turbidity can be abrasive to fish gill membranes,
20 preventing a fish in respiration. Increased water
21 temperatures could change important habitat areas,
22 making them unsuitable for fish adapted to very
23 cold environments. A permanent increase in water
24 temperature in some locations could be used to advantage
25 for agriculture, however, aquiculture, however,
26 since fish grow much more rapidly in warmer water.

27 A disruption of the
28 aquatic ecological balance in a particular system by
29 reducing certain species, removing food sources by
30 chemical contamination, or siltation, or introducing

C.T. Hatfield
In Chief

1 a new species into a watershed where it is not
2 native can also upset the system. Northern populations
3 are particularly susceptible to this sort of disruption
4 because of the relatively few species present and
5 therefore short food chains and simple inter-specific
6 relationships. Survival of northern fisheries is,
7 of course, dependent upon survival of the northern
8 fish populations. However, fish stocks can also be
9 chemically contaminated and made unfit for human
10 consumption by mercury, petroleum, copper, lead,
11 zinc, cadmium, pesticides, or polychlorinated
12 biphenols, or P.C.B.s, some of the things we were
13 talking about earlier today. It might not affect
14 the fish populations but it will affect the predator
15 eating the fish populations, i.e. in this case, man.

16 As one would expect, fish
17 resilience varies from species to species. As I
18 stated in the beginning of the paper, information is
19 scarce in this area, and direct tests on the effects
20 of life history, disruption, or the ability of
21 fish populations to recover from it, have hardly been
22 studied at all in the north. Information on fish
23 resilience, therefore, is mainly from that special
24 store of insight that biologists have and must often
25 use, professional speculation.

26 The spring spawner, Arctic
27 greyling and fall spawners, Arctic char, Pacific
28 salmon, lake trout, inconnu, humpback and broad white
29 fish and Arctic and least cisco appear to be the
30 least resilient northern fish because of their lower

C.T. Hatfield
In Chief

1 tolerance to turbidity particularly during spawning
2 than other species. Slow growth and narrow age
3 classes are also a problem in recovery. These species
4 are the most economically valuable in the domestic,
5 commercial and sports fisheries.

6 Northern pike, walleye,
7 long nose and white suckers, flathead chub and burbot
8 probably have relatively high resilience because of
9 the broad habitat tolerance and wide distribution.
10 The piscivorous or fish-eating species such as pike,
11 char, inconnu and burbot, would be most susceptible
12 to chemical contamination because of the passing of
13 most biological contaminants up the food chain and
14 the concentrating of it in the top levels.

15 Of course, as John Livingston
16 was saying, the birds can eat these fish and pick up
17 their contaminants from the fish.

18 In summary then, what are the
19 main points to remember about northern aquatic environ-
20 ments?

- 21 1. When water freezes, habitat for fishes is lost.
22 In order to survive the winter fish must locate
23 areas of unfrozen water. The water must also have
24 sufficient oxygen and low enough pollution levels
25 to allow the fish to survive.
- 26 2. Preliminary evidence suggests that winters do
27 vary significantly from year to year. Pools that
28 provide adequate over-wintering areas for fishes
29 in some years are not necessarily adequate in
30 other years. From this point of view the kind

In Chief

of winter when disturbance occurs is important.

3. Northern aquatic systems are simple in structure and very low in productivity. They are simple already. Additional stress at intermediate levels has very little noticeable effect. Significant additional stress at levels we don't yet understand, ~~we~~ have the ability to predict, results in the system breaking down.
4. The Mackenzie system as a whole is a unique aquatic system. Its diversity and extent, give it this uniqueness as a system, even though its component parts are duplicated in many areas. The Mackenzie system's current lack of pollution may be one of its most important attributes in the long run.
5. When fish concentrate in large numbers, they are more vulnerable to disruption caused by environmental change. Thus spawning grounds, over-wintering holes, and major migration routes of the different species are areas most important to this resource.
6. Spring breakup, fall freezeup, and winter are the most critical times of the year in the life histories of most species. Winter is an important time for the eggs of fall spawners which stay in the stream gravel until the spring.
7. Northern fishes have slow growth rates, are late to reach sexual maturity, have low species diversity, and have limited food supply. They are probably less resilient, therefore, to disruption than fishes of more southern latitudes. It takes

C.T. Hatfield
In Chief

- 1 northern fish populations longer to regain natural
2 levels after being reduced in numbers.
- 3 8. Northern fish species have life histories very
4 different from each other and within a species,
5 specific to each system in which ~~they~~ reside.
6 Fish population management and protection programs
7 therefore must consider the local geographic and
8 specie- specific characteristics of each fish
9 community.
- 10 9. Fish species requiring clean gravel requirements
11 and clean gravel for spawning are probably more
12 vulnerable to natural and man-made environmental
13 disruptions from siltation. To these populations,
14 clean gravel of an appropriate size ^{as} is important
15 to species survival as the water itself.
- 16 10. The coregonid or white fish family along with the
17 Arctic char, Arctic greyling and lake trout are
18 economically the most valuable species to northern
19 fisheries.
- 20 11. Domestic utilization of the resource by northern
21 people takes precedence over commercial or sports
22 use.
- 23 12. Finally our last point we come back to the theme
24 that Lee started, and that's point 12, because
25 water flows from place to place and organisms
26 live in most places water is found, we should think
27 of watersheds as a study unit.

Thanks very much, Mr.

Commissioner.

THE COMMISSIONER: Thank you,

C.T. Hatfield
In Chief

1 Mr. Hatfield. I certainly appreciate the graphic
2 and complete way in which Mr. Doran and you have pre-
3 sented this examination of northern aquatic systems.
4 Thank you very much.

5 (WITNESS ASIDE)

6 MR. SCOTT: I propose we
7 adjourn until nine o'clock tomorrow morning.

8 THE COMMISSIONER: Yes, we
9 stand adjourned until nine o'clock tomorrow morning.
